TABLE OF CONTENTS

Executive Summary **ES-1**

Section 1 Introduction **1-1**
1.1 Introduction 1-1
1.2 Project Purpose and Scope 1-1
1.3 Project Location 1-1
1.4 Fort Wingate Depot Activity History 1-2
1.5 Previous Investigations at Fort Wingate Depot Activity 1-2
1.6 Summary of Munitions and Explosives of Concern Risk 1-3
1.7 Report Organization 1-3

Section 2 IF Removal and Soil Sampling Activities **2-1**
2.1 Instrument Test Strip 2-1
2.2 Location Surveys 2-1
2.2.1 Munitions and Explosives of Concern Safety Provisions 2-1
2.2.2 Control Points 2-2
2.3 Vegetation Removal 2-2
2.4 Inner Fence MEC Removal Activities 2-2
2.4.1 Subsurface MEC, MPPEH and MD Removal 2-2
2.5 Minimum Separation Distances 2-6
2.5.1 Minimum Separation Distances for Intentional Detonations 2-6
2.5.2 Minimum Separation Distances for Unintentional Detonations 2-6
2.6 Disposal Techniques 2-6
2.6.1 Munitions and Explosives of Concern Disposal 2-6
2.6.2 Munitions and Explosives of Concern Transportation 2-7
2.6.3 Established Demolition Areas and Consolidated Shots 2-7
2.6.4 MEC Demolition Procedures 2-7
2.7 Corrective Action Management Unit Operation 2-8
2.8 Soil Characterization Sampling Activities 2-9
2.8.1 Soil Sampling Design for Low-Density MEC Areas and Buffer Areas 2-9
2.8.2 Low Density MEC Area Incremental Soil Sampling Procedures 2-11
2.8.3 Buffer Area Grid Incremental and Discrete Soil Sampling Procedures 2-13
2.9 Fieldwork Documentation 2-16

Section 3 MEC RA and Soil Sampling Results **3-1**
3.1 MEC Removal Action Results 3-1
3.2 Characterization Soil Sampling Results 3-1
3.3 Chemical Data Usability 3-2

Section 4 Human Health Risk Screening **4-1**
4.1 Human Health Risk Screen Approach 4-1

TABLE OF CONTENTS

4.1.1 Conceptual Site Model (CSM) 4-1
4.1.2 Comparison with Background 4-2
4.1.3 Soil Screening Levels 4-4
4.1.4 Target Risk Levels 4-4
4.1.5 Soil Exposure Intervals 4-4
4.1.6 Screening Evaluation Exposure Concentrations 4-4
4.1.7 Screening Evaluation 4-5
4.1.8 Calculation of Cumulative Human Health Risk 4-5
4.1.9 Risk Refinement 4-6
4.1.10 Dioxins/Furans 4-7
4.1.11 Evaluation of Lead Concentrations 4-7

1

EXECUTIVE SUMMARY

This Inner Fence (IF) Report presents the field activities and documents the results of a subsurface removal action (RA) of munitions and explosives of concern (MEC) and munitions debris (MD) from the IF area within Parcel 3 at Fort Wingate Depot Activity (FWDA). This Report complies with the FWDA Resource Conservation Recovery Act (RCRA) Permit Number NM6213820974 and the work was completed in accordance with the New Mexico Environment Department (NMED)-approved Final Work Plan (WP), Inner Fence, Parcel 3.

The work included completing a surface and subsurface MEC removal action and soil sampling activities for munitions constituents (MC) from within the IF. During the MEC RA, MEC (regardless of size) and metallic debris 1.5 inches by 3 inches or larger were removed from the subsurface along with any surface MEC or metallic debris. As anomalies were removed, they were inspected to determine if the anomaly was MEC, material documented as explosive hazard (MDEH), or material documented as safe (MDAS). All MEC and MDEH was further inspected to determine if it was acceptable to move. MEC and MDEH that was determined acceptable to move was transported to the earth covered magazines for storage until destruction at a later date at the CAMU. Items that were determined unacceptable to move were destroyed by detonation in place.

The CAMU, located in Parcel 3, SWMU 14, operates under Section IX of the FWDA RCRA Permit for the destruction of MEC. CAMU operations included detonations and burning as determined by the nature of the MEC. MEC and MDEH were disposed. After demolition operations, the remaining debris was inspected to verify that it was MDAS. MDAS that was removed from the IF and from demolition activities was flashed and stored in locked and sealed roll-offs for recycling.

The subsurface RA of the IF began on August 28, 2017, and ceased in December 2020 due to concerns for personnel safety. The anomaly densities encountered were determined to be too high to safely identify and manually resolve as single point anomalies. It was concluded that the anomaly densities would continue to increase as the RA moved closer to the HWMU and the remainder of the IF subsurface RA, therefore, required alternative methods to complete.

Before the work ceased, over 1.4 million anomalies were investigated and over 338,8000 pounds of MD was recovered from the IF. A total of 16,578 MEC items were identified and recovered from the IF. The majority of MEC items recovered were point detonating (PD) and base detonating (BD) fuzes, 37 mm, and 40 mm projectiles. These four items accounted for nearly 85 percent of the MEC recovered from the IF.

Soil sampling of low-density MEC areas within the IF was added to the work to address an NMED request that either historical data be provided to show that residual contamination associated with lower density clusters and individual items are insignificant with respect to risk or sample a percentage of low-density grids. Soil sampling of the “buffer areas” immediately bounding the HWMU/high-density grids was also added to the work to address a NMED Notice of Disapproval Letter (dated July 1, 2020).

EXECUTIVE SUMMARY

IF soils were characterized using a combination of incremental and discrete sampling. Incremental Sampling Method (ISM) samples were collected from grids within the low-density area and grids within the buffer area and analyzed for explosives and metals. Additionally, discrete samples were collected from each buffer area grid where an ISM was collected and analyzed for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), N-Nitrosodimethylamine (NDMA), polychlorinated biphenyls (PCBs), nitrate, cyanide, dioxins/furans, and perchlorate (Method 6850).

ISM soil samples were collected from 94 low-density area grids and ISM and discrete samples were collected from 76 buffer area grids. The analytical results for these samples were evaluated for human health and ecological risks. None of the low density grids posed unacceptable cancer risks or adverse health effects for the industrial worker scenario. Several grids showed potentially unacceptable cancer risks (>1.0E-05) or adverse health effects (HQ/HI greater than 1.0) for residents and/or construction workers. The primary contributors for all these grids were metals, specifically aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium. The target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0. Therefore, these grids were considered to pose no unacceptable adverse health effects to residents or construction workers for non-cancer risks. Several grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese resulted in hazards greater than 1.0 for the construction worker scenario. Manganese concentrations in these low density grids may be naturally-occurring and not related to site activities and grid risk/hazards may been over estimated. Arsenic was detected in one low density area sample at a concentration that exceeded its cancer risk for residents, however the concentration was within the background range for FWDA and was considered naturally occurring. All other samples had cancer risks less than the NMED target cancer risk of 1.0E-05 and non-cancer risk less than the NMED target HI of 1.0.

Excess cancer risks for all 76 buffer grids were below the NMED target cancer risk of 1.0E-05. All industrial worker hazard indices were below 1.0. Several buffer area grids showed the potential for adverse health effects (HQ/HI greater than 1.0) for residents and/or construction workers. The primary contributors for all these grids were metals, specifically aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium. The target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0. Therefore, these buffer area grids were considered to pose no unacceptable adverse health effects to residents or construction workers. Several buffer area grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese or manganese individually resulted in hazard greater than 1.0 for the construction worker scenario. The aluminum and manganese concentrations in these buffer area grids may be naturally-occurring and not related to site activities and grid risk/hazards may been over estimated.

All detected lead concentrations in the low density and buffer area grids were below the NMED residential SSL (200 mg/kg); therefore, no further evaluation of lead concentrations was necessary.

The soil-to-groundwater migration pathway evaluation showed detected concentrations of some VOCs and explosives have the potential to impact groundwater depending on the depth to groundwater in the vicinity of the grids.

An ecological risk assessment was completed and determined that the IF contains terrestrial ecological habitat and potentially complete pathways for ecological receptors. Metals were identified as posing the greatest ecological risk potential within the IF following a Tier 1 evaluation. As a result, a Tier 2 SLERA was also completed and concluded that there are no unacceptable ecological risks to the viabilities and functions of the omnivorous mammal populations or carnivorous bird populations within the IF Area. The HI for terrestrial plants and the horned lark exceeded 1.0 in the Tier 2 evaluation. The HI values were driven by metals. Calculation of background metal concentrations also exceeded 1.0. Therefore, the potential for adverse effects for the terrestrial plant community and omnivorous bird populations may be due to non-site related naturally-occurring concentrations of metals.

1.1 INTRODUCTION

This Inner Fence (IF) Report has been prepared to present the field activities and document the results of a subsurface removal action (RA) of munitions and explosives of concern (MEC) and munitions debris (MD) from the IF of Parcel 3 at Fort Wingate Depot Activity (FWDA).

This Report was prepared to comply with the FWDA Resource Conservation Recovery Act (RCRA) Permit Number NM6213820974. The work was completed in accordance with the New Mexico Environment Department (NMED)-approved Final Work Plan (WP), Inner Fence, Parcel 3 (AECOM 2021). This work was completed under the direction of the United States (U.S.) Army Corps of Engineers (USACE) to implement the United States Army's Base Realignment and Closure (BRAC) mission to close the FWDA and return to the withdrawn public lands.

1.2 PROJECT PURPOSE AND SCOPE

The objective of this RA was to complete a subsurface MEC removal over approximately 319 acres of the IF in accordance with the RCRA Permit Sections IV.C and IV.F, and to locate, identify, and remove MEC and material potentially presenting an explosive hazard (MPPEH), including MD and range-related debris (RRD) from the IF. The cleanup criteria for the IF were to remove all MEC (regardless of size) and metallic debris 1.5 inches by 3 inches or larger. The primary tasks included in the following:

- IF boundary establishment
- Subsurface removal of MEC and MD to depth of detection
- MPPEH inspection
- MEC disposal operations
- MD flashing
- Material documented as safe (MDAS) disposal
- Characterization soil sampling
- Reporting, including human health and ecological risk assessment

1.3 PROJECT LOCATION

FWDA is located in northwestern New Mexico in McKinley County, approximately 8 miles east of Gallup, New Mexico (**Figure 1-1**). FWDA currently occupies approximately 24 square miles (15,273 acres) of land with facilities formerly used to operate a reserve storage facility that provided for the care, preservation, minor maintenance, and disposal of primarily conventional military munitions.

The IF is located within Parcel 3 and includes approximately 319 acres of land immediately adjacent to the Hazardous Waste Management Unit (HWMU). The location of the IF is shown on **Figure 1-2** along with other Site details.

1.4 FORT WINGATE DEPOT ACTIVITY HISTORY

The FWDA was originally established by the Army in 1862. In 1918, the mission of the FWDA changed from tribal activities to World War I related activities. Beginning in 1940, the FWDA's primary mission was to receive, store, maintain, and ship explosives and military munitions, as well as disassemble and dispose of unserviceable or obsolete explosives and other military munitions. In January 1993, the active mission of the FWDA ceased, and the installation closed as a result of the Defense BRAC Act of 1990. In 2005, environmental activities began under the United States Environmental Protection Agency (USEPA) Permit identification (ID) Number (No.) New Mexico (NM) 6213820974 (FWDA RCRA Permit), which was finalized in December 2005 (NMED 2005). In February 2015, Permit NM6213820974 was modified for activities in the Corrective Action Management Unit (CAMU) located in Parcel 3. FWDA is currently undergoing final environmental characterization and restoration activities prior to final property transfer/return and reuse.

1.5 PREVIOUS INVESTIGATIONS AT FORT WINGATE DEPOT ACTIVITY

In 1995, UXB International, Inc. (under contract to USACE Huntsville District) conducted a MEC clearance to a depth of 1 foot in 512 grids, each measuring 100 feet x 200 feet along 6,600 feet of the western boundary (a portion of the proposed fence corridor) of Parcel 3. Sixty-nine live items were recovered and disposed of ranging from tracers to 90-millimeter (mm) high-explosive (HE) projectiles (models unknown). Eleven items found required blow in place (BIP) procedures. These MEC items included five M83 fragmentation "Butterfly" bomblets, one 40mm HE projectile, two 75mm projectiles, one M66A1 base fuze, one 3.5-inch rocket fuze, and one base fuze/booster (model unknown).

From November 1998 to May 1999, Environmental Hazards Specialists International, Inc. performed MEC location and removal actions at FWDA. They conducted a surface removal action of 82, 200 foot x 200 foot grids, and a subsurface removal action to a depth of four feet below ground surface (bgs) of 88 grids (typically 200 foot x 200 foot grids but some had irregular shapes and sizes). Of the 337 items recovered, 32 were MEC. The 32 MEC items included seven 60mm mortars, one M404 fuze, three 57mm armor piercing HE, five 40mm projectiles, two 75mm projectiles, four 37mm projectiles, two M83 fragmentation "Butterfly" bomblets, one M1 burster, one miscellaneous fuze component, two M66 base detonating fuzes, and four M148 fuzes.

In 2001, USA Environmental, Inc., performed MEC fence line construction support at FWDA, which included locating, identifying, and disposing of items.

In 2009, in accordance with the RCRA Permit Section IV.A, Confirmation of the Kickout Area (KOA) was completed and the KOA outer boundary was delineated. This delineation estimated outer boundary by conducting radial transect investigations and adding 275 feet from the furthest detected waste military munition (WMM) or WMM scrap. The Army provided NMED a Site-Specific Final Report (PIKA 2009) to document this delineation. This Report was accepted by the USACE and approved by NMED. The present estimated KOA boundary included Parcel 3, portions of Parcel 1 to the south, Parcel 2 to the north, and Parcel 20 to the east, as well as a segment of Trust Lands bordering the western side of the FWDA Facility.

In 2015 a surface removal action of MEC and MD was initiated within designated areas of the KOA (PIKA Pirnie 2015), including the IF. The work was suspended in 2018 before the surface RA of the IF was completed.

1.6 SUMMARY OF MUNITIONS AND EXPLOSIVES OF CONCERN RISK

Parcel 3 is confirmed to contain Improved Conventional Munitions (ICMs). MEC and MPPEH items identified at the Parcel 3 project site (including the IF as shown on **Figure 1-2**) have included a wide range of ICMs (e.g., Bomb Live Unit (BLU)-3 and BLU-4 bomblets). Other munitions reportedly demolished in Parcel 3 have included M83(s); projectiles ranging from 20mm to 240mm; bombs ranging from 3 to 10,000 pounds; and assorted rockets, mortars, missiles, land mines, grenades, flares, and bulk explosives.

1.7 REPORT ORGANIZATION

This Report consists of seven sections and associated appendices summarized as follows:

- **Section 1:** Presents the project scope, location and summarizes historical investigation and remedial activities.
- **Section 2:** Describes the IF RA activities, including MEC removal procedures, MPPEH procedures, MEC disposal procedures and soil characterization sampling activities.
- **Section 3:** Summarizes the quantities of MEC and MD recovered during the RA and the soil sampling analytical results.
- **Section 4:** Presents the methodology and results of the human health risk analysis.
- **Section 5:** Present the methodology and results of the ecological risk analysis.
- **Section 6:** Summarizes the work completed within the IF, the results of the soil analytical results and the human health and ecological risk analyses.
- **Section 7:** References
- **Appendix A**: Field Documentation.
- **Appendix B**: Soil Analytical Results.
- **Appendix C**: Laboratory Reports and Data Validation.

- **Appendix D**: Risk Assessment

This section presents a summary of the IF MEC removal and surface soil sampling activities, including descriptions of the removal methods, removal areas, and surface soil sampling procedures and locations.

2.1 INSTRUMENT TEST STRIP

An instrument test strip (ITS) was established to verify detector equipment functionality and to simulate the techniques required to detect MEC in the IF. Each unexploded ordnance (UXO) technician swept the ITS at the beginning of fieldwork activities each day using his/her assigned analog geophysical instrument. Whites XLT or equivalent all-metals detectors were typically used for subsurface removal operations along with Schonstedt magnetometers.

The ITS was a Quality Control (QC) measure that demonstrated the functionality of the detection equipment used during the RA and the ability of the equipment operator to detect items encountered in the IF. The ITS was approximately 50 feet long and 5 feet wide and was cleared of all anomalies prior to installation. The Unexploded Ordnance Quality Control Specialist (UXOQCS) placed small, medium, and large Industry Standard Objects (ISOs) at various depths and orientations within the ITS. The ISOs were schedule 40 pipe nipples made from black welded steel, manufactured to American Society for Testing and Materials specification. The ITS included six industry standard objects (ISOs) buried along a linear path as follows:

- Three small ISOs (i.e., 4-inch X 1-inch) were buried at approximate depths of 2 inches, 4 inches, and 6 inches, respectively. Two were buried in an orientation that was horizontal to the ground surface and the third was buried vertically.

- Two medium ISOs (i.e., 8-inch X 2-inch) were buried at approximate depths of 6 inches and 10 inches. Both were buried horizontal to the ground surface.

- One large ISO (i.e., 12-inch X 4-inch) was buried at an approximate depth of 18 inches with an orientation that was horizontal to the ground surface.

If an instrument was not functioning properly during the daily function test, it was removed from service for repair and replaced with a properly functioning instrument.

2.2 LOCATION SURVEYS

The existing boundary and grid system that was established for the KOA RA was used for the IF RA (PIKA Pirnie 2015). No additional permanent monuments or markers were established.

2.2.1 Munitions and Explosives of Concern Safety Provisions

During all surveying operations, the survey crew was accompanied by a UXO escort implementing MEC and anomaly avoidance procedures in accordance with EM 385-1-97,

Change 1. The UXO technician perform a visual survey for surface MEC before the survey crew enters the area.

2.2.2 Control Points

Inner fence control points were established within Parcel 3 using real-time kinematic (RTK) survey and the Online Positioning User Service (OPUS) to support centimeter-level GPS positioning and data collection. They were used to set inner fence grid corners and for daily QC checks of GPS equipment.

2.3 VEGETATION REMOVAL

Areas containing low-lying or sparse vegetation did not require vegetation removal. UXO technicians removed vegetation from areas as required for safe performance of an activity, access to MEC, demolition of UXO, or fire prevention prior to demolition efforts.

Prior to, and during vegetation removal, UXO technicians visually inspected the area where the vegetation removal was needed to verify the area was free of surface MEC items or other items that may present a physical hazard. During vegetation removal, site personnel utilized the safety and health personal protective equipment (PPE) specified in the Accident Prevention Plan (APP) and required by EM 385-1-1. Vegetation was cut no closer than six inches from the ground surface and attention was paid so as not to remove any root ball of the vegetation being cut. Cut vegetation was removed from the immediate work area and placed outside of the area to decompose naturally. All vegetation removal activities were completed in accordance with EM-385-1-1, Section 31.

2.4 INNER FENCE MEC REMOVAL ACTIVITIES

A MEC surface clearance within the IF was previously initiated under a separate contract (PIKA Pirnie 2015) prior to the execution of this subsurface MEC RA. The MEC surface clearance was suspended in 2018 before it was completed; therefore, the subsurface RA was limited to those areas where the surface clearance had been completed. For the safety of site personnel, the RA was not completed in areas with slopes greater than 30 percent. The IF grid layout, grid ID numbers, and locations of slopes greater than 30 percent (i.e., inaccessible areas) are shown on **Figure 2-1**. During subsurface removal operations, UXO technicians used all-metals detectors to locate metallic anomalies in the subsurface as described in the following subsections.

2.4.1 Subsurface MEC, MPPEH and MD Removal

The UXO clearance teams completed a manual MEC subsurface clearance to depth of detection within the IF, excluding the HWMU and AOC 92. As is further detailed in **Section 3.1**, the IF grids/areas shown in white on **Figure 2-2** were not cleared by the manual excavation methods employed during this RA. The anomaly densities within these grids/areas were too high to be able to safely identify and manually resolve single point anomalies. Some of these IF grids

(especially grids west of the HWMU boundary up to the western boundary of the inner fence area) were added to the scope of the mechanical excavation and soil processing activities completed as part of the mechanized RA at the adjacent HWMU.

During the IF MEC RA, MEC (regardless of size) and metallic debris 1.5 inches by 3 inches or larger were removed from the subsurface along with any surface MEC or metallic debris that was missed during the previous surface clearance activities. Upon arrival at an assigned grid, the UXO dig team leader verified the location and reinstalled any missing grid stakes, as needed. Team members marked control lanes with rope. Control lanes ran north to south and were approximately 4 feet in width, with some variations based on terrain and vegetation hazards. During grid clearance operations, the UXO Technicians swept the instruments through their respective lanes in a tight forward pattern, following the contours of the terrain and ensuring complete area coverage.

Subsurface target anomalies that met the NMED approved clearance criteria (MEC [regardless of size] and metallic debris measuring 1.5 inches by 3 inches or larger) were removed. Identified subsurface anomalies were manually excavated in accordance with EM 385-1-97 (USACE 2008) to determine the anomaly source. At no time did UXO technicians dig directly over an anomaly until its depth had been determined by digging to the side of the anomaly. Once the anomaly was located, it was visually inspected, identified, and assessed for hazards by two qualified UXO technicians, one of whom was a UXO technician III (UXOTIII). Target anomaly locations were rechecked after the removal of the anomaly to verify the anomaly was completely removed and was not masking anything beneath it. Once the target anomaly location was resolved, any excavated soil was backfilled. If MEC was discovered, it was marked and managed in accordance with the procedures described in EM 385-1-97, Change 1.

2.4.1.1 Munitions and Explosives of Concern Items Encountered

The MEC identification process started when the anomaly was located. When the UXO technician that located the item identified it as MEC, a UXOTIII confirmed the item was MEC. Once the item was confirmed as MEC, it was marked with a pin flag, and the Senior UXO Supervisor (SUXOS) and Unexploded Safety Officer (UXOSO) were notified and requested to determine if the MEC item was acceptable to move. If the MEC item was determined acceptable to move, it was transported to the earth-covered magazines (ECMs) for storage until later destruction at the CAMU. If the item was determined unacceptable to move, it was BIP. The USACE Ordnance and Explosives Safety Specialist (OESS) was notified and assistance requested if personnel could not make a positive identification.

Prior to removal or disposal, the location of each MEC item and all relevant information related to the item was recorded with GPS equipment. Data associated with MEC locations included:

- The grid number where the item was found.
- Item number assigned.
- Type of item.

- Location of item in coordinates.
- Depth below ground surface.
- Digital photograph and disposition.

Post-MEC disposal actions included the implementation of the MPPEH inspection process on any remaining material at the shot location. If the MPPEH had an explosive hazard it was designated as MDEH, if not, it was designated as MDAS. Items designated as MDEH underwent explosives demolition operations as described in **Section 2.6**.

2.4.1.2 Material Potentially Presenting an Explosive Hazard Inspection and Munitions Debris and Range Related Debris Storage

All suspected MPPEH was 100 percent inspected by the UXO Field Team. Two separate UXO Qualified Person (UXOQP) conducted the inspections prior to removing any material from the grid. At a minimum, a UXOTII completed a 100 percent inspection and a UXOTIII completed a 100 percent re-inspection to determine if the item was MDEH, or MDAS (including MD or RRD) and verified it did not contain an explosive hazard. Items designated as MDEH underwent explosive demolition operations as described **Section 2.6**. MDAS segregated as MD and RRD were kept in sealed and locked roll-off containers until final disposition.

The SUXOS performed random spot checks to verify the inspection procedures were being implemented, that all MD and RRD were free of explosive hazards, were properly segregated from other material to prevent comingling, and were secured in the secured roll-off containers. The UXOQCS conducted daily audits of the above procedures for processing MPPEH, MD, and RRD to verify compliance with the WP. The UXOQCS performed random inspections of designated MDAS, MD, or RRD, to verify no items containing explosive hazards were being comingled with the inspected MDAS, MD, or RRD.

Inspected and certified MDAS, including MD and RRD were secured in locked roll-off containers until final disposition to prevent comingling MD or RRD with material that had not been inspected. The containers were lockable, clearly labeled on the outside with the following information: Unique identification that included the USACE/Installation Name/Contractor's Name/0001/Seals unique identification and continue sequentially for each additional container used for the same project site. The seal was attached to the container in such a manner that the container could not be opened without damaging the seal.

2.4.1.3 MDAS Final Disposition

The SUXOS certified the MDAS was free of explosive hazards and the OESS verified the MPPEH inspection process had been followed. Form 1348-1A was used to document the description of each container and was also used as the certification/verification documentation for each container of MDAS. Form 1348-1A included typed or printed names of the SUXOS and UXOQCS, organization, signature, contractor's home office, and the field office phone

number(s) of the persons certifying and verifying the debris as free of explosive hazards. The Forms also included:

- Basic material content (e.g., steel or mixed metal).
- Estimated weight.
- Unique identification of each of the containers and seals stated as being turned over.
- Location where MDAS was obtained.
- Seal identification, if different from the unique identification of the sealed container.

The following certification/verification was entered on each Form 1348-1A for turnover of MD or RRD and was signed by the SUXOS and the OESS. The statement below was used when RRD was processed along with MD:

- "This certifies that the material listed has been 100 percent properly inspected and, to the best of our knowledge and belief, is free of explosive hazards, engine fluids, illuminating dials and other visible liquid hazardous, toxic, and radioactive waste (HTRW) materials."

The following certification/verification was entered on each Form 1348-1A for turnover of MDAS and was signed by the OESS. This statement was used when only MD was processed:

- "This certifies that the material listed has been 100 percent inspected and, to the best of our knowledge and belief, are inert and/or free of explosives or related materials."

The chain of custody (COC) was maintained and final disposition of the certified and verified materials was documented. The certified and verified material was released to a recycler that would:

- Receive a secured labeled container, with its unique identified and unbroken seal (ensuring continuity in the COC), review and concur with the supporting documentation, sign for having received and concurred with the documentation that the secured container contained no explosive hazards upon receipt. Concurrence was provided on the recycler's company letterhead and clearly stated that the contents of the sealed container were not sold, traded, or otherwise given to another party until the contents were smelted and were only identifiable by their basic content.
- Provide documentation that the contents of the sealed container had been smelted and were only identifiable by their basic content.

2.4.1.4 Quality Control and Quality Assurance Activities

Blind seeds were placed within each grid by the UXOQCS. The blind seeding was a QC measure to verify the functionality of the detection equipment and ability of the UXO technicians to detect and remove subsurface anomalies. The UXOQCS placed up to 2 large blind seeds and 3 small seeds per operator per Lot (10 contiguous grids). Each seed was given a unique ID so the UXOQCS could verify that all seeds from within a grid were recovered. Upon completion

the subsurface removal within a grid, it was turned over to the UXOQCS for follow-up inspection. The UXOQCS verified that all blind seeds had been removed from the grid and inspected a minimum of 10 percent of the grid to verify that the work met the project performance objectives.

Upon completion of QC inspection, grids were turned over to the OESS, in Lots of 10, for Quality Assurance (QA) inspection. The OESS placed additional QA blinds seeds, randomly inspected each Lot, and verified all QC and QA seeds had been recovered. Upon verifying the Lot met the project performance requirements, the OESS provided a Form 6048 documenting government acceptance of the work.

2.5 MINIMUM SEPARATION DISTANCES

2.5.1 Minimum Separation Distances for Intentional Detonations

The applicable minimum safe distances (MSDs) for intentional detonations for the IF are presented in the Department of Defense Explosives Safety Board (DDESB) approved Explosive Safety Submission (ESS). During MEC operations, the SUXOS, UXOSO, and UXO team leaders established and maintained applicable MSDs, based on the nature of the activity, in accordance with the ESS. All MSD restrictions were established and enforced for all personnel during all operations.

2.5.2 Minimum Separation Distances for Unintentional Detonations

The applicable MSDs for unintentional detonations (i.e., accidental explosions) for the IF are presented in the DDESB-approved ESS. Preliminary site work such as surveying did not require an MSD. The MSD restrictions during MEC operations applied to all non-essential personnel. Essential personnel are defined as those Army and subcontractor personnel essential to the safe and effective performance of the MEC removal activities along with those approved and authorized visitors; all others are designated as non-essential.

2.6 DISPOSAL TECHNIQUES

2.6.1 Munitions and Explosives of Concern Disposal

All MEC encountered during the RA was properly disposed. MEC disposal operations were supervised by the SUXOS and coordinated with the OESS. MEC disposal operations were conducted in accordance with USACE EM 385-1-97, Change 1, Explosives Safety and Health Requirements Manual.

MEC demolition procedures are presented **Section 2.6.4**. Physical control of the on-site disposal operations was accomplished by blocking access roads to the disposal location at the point of the exclusion zone (EZ). Control of disposal operations were maintained to prevent unauthorized access by non-essential personnel. During disposal preparation, all non-essential personnel

evacuated outside the applicable MSD and all essential personnel were evacuated to a designated safe location prior to the initiation of the disposal shot.

The number of essential personnel used during disposal operations was kept to the minimum required to safely accomplish the disposal task.

2.6.2 Munitions and Explosives of Concern Transportation

For MEC encountered that was determined unacceptable to move, BIP operations were conducted. When MEC was determined acceptable to move, transportation of MEC was done in a vehicle equipped and placarded to transport explosives. MEC determined acceptable to move was relocated to the secured ECMs until later disposal at the CAMU.

2.6.3 Established Demolition Areas and Consolidated Shots

The CAMU is the only established demolition area at FWDA and was used for destruction of MEC by denotation or burning. For consolidated MEC disposal shots at the CAMU, the USAESCH publication "Procedures for Demolition of Multiple Rounds (Consolidated Shots) on Ordnance and Explosives (OE) Sites," dated March 2000 was followed. The maximum net explosive weight (NEW) for a consolidated shot was limited such that the K328 overpressure distance for the total NEW (including donor charges) did not exceed the MSD for the intentional detonation.

2.6.4 MEC Demolition Procedures

Prior to beginning disposal operations, an exclusion zone was established around the demolition activity. Exclusion zones were based on MSD calculations for the specific item requiring disposal or the MSD established in the ESS. For consolidated shots, the MSD was selected based upon either the cumulative NEW overpressure distance or the appropriate fragment range, whichever was greater.

Electric demolition, remote firing device, and shock tube/nonelectric (NONEL) are the three methods that were used for demolition operations. The operations were completed in accordance with Technical Manual (TM) A-1-1-31 and are generally described below:

- Once the demolition charges were primed and set, and after all personnel had returned to the firing point, a head count was taken. The team verified that all notifications had been made and all site personnel were outside of the MSD.
- Safety signals were used in accordance with EM 385-1-1.
- If there was no response from the verbal notification, the charge was initiated.
- After the detonation, a 5-minute wait time was observed.
- After the 5-minute wait time, the Demolition Team Leader and one other UXOQP proceeded to the shot location. One person inspected the shot location, and the second remained at a

safe distance to render assistance or aid, if required. The team completed a thorough search of the shot location immediate area with a magnetometer to verify that complete demolition was accomplished.

- The SUXOS notified all personnel with an audible "all clear" that the shot was complete and personnel may open access roads as applicable.

The following was observed during demolition activities:

- The number of persons involved in MEC disposal operations was kept to a minimum, consistent with safe performance of the work. Personnel were not allowed to work alone.
- Only the Demolition Team, OESS, SUXOS, UXOSO, and UXOQCS were permitted in the area where charges were assembled and demolition operations were conducted.
- MEC disposal operations did not commence without functioning communications between all disposal team members. The audible signals described in EM 385-1-1, Paragraph 29.H.04 were sounded before any demolition shot.
- All access roads to the demolition location were secured and the area visually checked for any unauthorized personnel.
- All demolition shots complied with the authorized explosive limits and safe separation distances.
- Explosive demolition operations were discontinued when an unforeseen hazardous condition developed and did not resume until the condition was corrected.
- Smoking, matches, electronic cigarettes, or other flame-producing materials were not permitted within 100 feet of an area in which explosives were handled.
- In addition to the demolition team vehicle, an assigned emergency vehicle was staged in the area during demolition operations.
- Demolition operations were conducted during daylight hours only.
- Donor explosives and MEC were protected from the elements and static electricity.
- Only authorized spark-resistant tools were used within 15 feet of exposed energetic materials.
- MEC was not used for donor charges in demolition operations.

2.7 CORRECTIVE ACTION MANAGEMENT UNIT OPERATION

The CAMU, located in Parcel 3, SWMU 14, operates under Section IX of the FWDA RCRA Permit for the destruction of MEC. CAMU operations included detonations and burning as determined by the nature of the MEC. MEC, explosive components, and other associated components such as propellants, bulk explosives, metal powders, detonators, and miscellaneous munitions constituents (MC) were disposed.

During periods of CAMU operation, dry grass, leaves, and other flammable vegetation were removed for a distance of at least 200 feet from the CAMU cells. Live vegetation was maintained at a height of six inches or less within 200 feet of the CAMU cells. The CAMU was cleared at conclusion of each disposal event by removing the ash after each burn, and all scrap and MD after each detonation.

The amount of MEC treated at the CAMU did not exceed 200 pounds NEW per event or 1,000 pounds NEW in any seven-day period. A log was maintained detailing NEW consumption of donor charges and MEC per event/day/week by type, location, and methodology. It is important to note that, at the same time that MEC items recovered from the IF were being treated, disposed, and logged at the CAMU, MEC items recovered from the HWMU RA and found on other FWDA Parcels (i.e., by USACE and other contractors) were also being treated, disposed, and logged at the CAMU. A log specific to the items recovered from the IF area was not maintained.

2.8 SOIL CHARACTERIZATION SAMPLING ACTIVITIES

The soil sampling of low-density MEC areas within the IF was added to the Work Plan in response to the NMED Approval with Modifications Letter (dated September 18, 2018). NMED requested that either historical data be provided to show that residual contamination associated with lower density clusters and individual items are insignificant with respect to risk or complete additional sampling of a percentage of low-density grids. In response to the NMED Notice of Disapproval Letter (dated July 1, 2020), soil sampling of the "buffer areas" immediately bounding the HWMU/high-density grids was also added to the Work Plan.

IF soils were characterized using a combination of incremental and discrete sampling. Incremental Sampling Method (ISM) samples were collected from grids within the low-density area and grids within the buffer area. Additionally, discrete samples were collected from each buffer area grid where a ISM was collected.

The purpose of soil sampling was to determine if MC concentrations in soil exceeded Soil Screening Levels (SSLs) and if residual soil contamination poses a risk to human and ecological receptors. The low-density grids and the buffer area grids are shown on **Figure 2-2**.

Risk screening used to evaluate soil sampling results follows the 2022 NMED Risk Assessment Guidance (NMED 2022) and NMED Ecological Risk Assessment Guidance (2017). The sample risk screening methodology and results are presented in **Sections 4** and **5**.

2.8.1 Soil Sampling Design for Low-Density MEC Areas and Buffer Areas

2.8.1.1 Low-Density MEC Area

Visual Sample Plan (VSP) software was used to determine the quantity of samples required to statistically demonstrate if residual contamination poses a risk to receptors. VSP software

supports the development of a defensible sampling plan based on statistical sampling theory and the statistical analysis of sample results to support confident decision making.

Based on the release mechanism and conditions within the IF (i.e., dispersion of MEC from open burn/open detonation (OB/OD) activities at the HWMU resulting in surface area releases), incremental soil sampling was performed. The "*Show That At Least Some High % of The Sampling Area Is Acceptable, Presence/Absence Sampling*" Module was used to develop the number of incremental soil samples needed to characterize the low-density MEC areas. This VSP module inputs included the number of potential sampling grids (e.g., 100-foot by 100-foot MEC removal grids) within a decision unit (e.g., low-density MEC area of the IF) and calculated the quantity of samples needed to achieve a specified level of confidence that the condition of the decision unit was acceptable (e.g., below SSLs).

The VSP assumptions and inputs included:

- The IF is approximately 319 acres; however, approximately 68 acres were expected to be classified as unsafe to complete a manual MEC RA based on preliminary inspection of site conditions by the contractor in consultation with the onsite OESS. Therefore, 251 acres of low-density MEC areas (approximately **1,004 grids**) were used in VSP model.
- The 100-foot by 100-foot sampling unit size was selected so that sampling units would correspond to the subsurface MEC removal grids, which was the basis for identifying and documenting low-density MEC areas from high-density MEC areas (i.e., the decision to classify areas as low-MEC density or high-MEC density areas was made on a grid-by grid basis). Additionally, a 100-foot by 100-foot grid is approximately 0.25-acre in size, which is smaller than a typical residential lot used in the NMED risk guidance (i.e., a conservative approach).
- VSP confidence inputs were as follows: 1) **95 percent confidence** that at least **97 percent** of the grids in the decision unit were acceptable (i.e., below SSLs).

To provide a 95 percent confidence that 97 percent of all low-density MEC areas/grids are acceptable (i.e., below SSLs), about 94 low-density MEC grids within the IF required sampling.

When the MEC RA ceased in December 2020, the size of the low density MEC area was revised to 170 acres, based on actual site conditions. Running the same VSP module with a low density MEC area of 170 acres and all other VSP inputs from above unchanged, to provide a 95 percent confidence that 97 percent of all low-density MEC area grids were acceptable (i.e., below SSLs), an estimated 93 low-density MEC grids within the IF required sampling.

A total of 94 sampling locations were, therefore, selected from the IF using a random number generator. The low-density area grids were sampled for target analyte (TAL) metals by Method 6010B/6020A/7471B, and explosives by Method 8330B. The locations of the low-density area grids are shown on **Figure 2-2**.

2.8.1.2 Buffer Area

In response to the NMED Notice of Disapproval Letter (dated July 1, 2020), to the Inner Fence Work Plan, soil sampling of the buffer area was added to the Work Plan. The NMED stated to revise the sampling approach to include "buffer area" grid sampling. The buffer area was defined as grids immediately adjacent to the HWMU or high MEC density areas (i.e., the grids immediately adjacent to the area determined unsafe to excavate MEC manually).

A total of 76 buffer area grids were sampled and are shown on **Figure 2-2**. ISM samples were collected from the buffer area grids and analyzed for TAL metals (Method 6010B/6020A/7471B) and explosives (Method 8330B). Additionally, a discrete soil sample was collected from the approximate center of each buffer area grid and analyzed for volatile organic compounds (VOCs) (Method 8260B), semi-volatile organic compounds (SVOCs) (Method 8270D), N-Nitrosodimethylamine (NDMA) (Method 8270 SIM), polychlorinated biphenyls (PCBs) (Method 8082A), nitrate (Method 9056A), cyanide (Method 9014), dioxins/furans (Method 8290), and perchlorate (Method 6850).

During execution of the buffer area sampling, samples were not collected from the southern half and much of the western boundary of the IF. Buffer area samples were not collected from these grids because they were determined to be high-density grids and had not been cleared of MEC and debris.

2.8.2 Low Density MEC Area Incremental Soil Sampling Procedures

Incremental sampling was completed using a systematic random sampling approach as described in the Interstate Technology and Regulatory Council (ITRC) incremental soil sampling guidance (ITRC 2012, including January 2020 Clarifications). The grids that were established for the MEC removal work were also used as incremental sampling units (i.e., typically 100 feet by 100 feet). Once the boundaries of the sampling units were established, sampling personnel laid out the systematic random sampling pattern within each grid cell. After a location was cleared for sampling by a UXO technician, that soil increment was collected. This process was repeated until all increments within a sampling unit were collected.

2.8.2.1 Sampling Equipment

Soil was collected using disposable tools, including plastic disposable hand trowels, ziptop bags, and disposable scoops and glass jars for analytical samples. Sample volumes, container types, and preservation requirements were followed per specific method requirements in accordance with USEPA SW-846.

2.8.2.2 Sample Identification

Each sample was identified by a unique ID number that included the parcel number, site identifier, matrix, sample location identifier, and grid number. The sample parcel number was P3 and the site identifier was "IF" for Inner Fence. The source of the sample was "SS" for

surface soil. The type of sample was "IS" for incremental sample. The matrix was "SO" for soil.

An example of the sample ID for an incremental sample collected from grid U532 from within Inner Fence is P3IF-SS-IS-SO-U532. Matrix Spike/Matrix Spike Duplicate (MS/MSD) samples were given the same sample ID as the analytical sample but had "MS/MSD" written on their respective labels. Field replicate samples were blind samples to the laboratory and were given a unique sample ID. "500" and "600" were added to sample ID numbers to signify them as a first replicate and second replicate sample, respectively.

2.8.2.3 Soil Sample Collection

Incremental soil samples were collected from the 0 to 0.5-foot interval using the following procedure:

- A UXO Technician cleared each sampling location/grid immediately prior to sampling and offset the sample location as necessary to avoid any metallic anomalies in accordance with EM 385-1-97.
- The soil sampler donned a clean pair of nitrile gloves.
- Collected 30 to 50 grams of soil from the 0 to 0.5-foot interval at each sample increment location. using a plastic disposable scoop such that an equal volume of soil could be collected from each ISM increment location. Each increment was added to a plastic bag carried in a one-gallon plastic bucket to protect the plastic bag from damage. The same trowel and scoop were used to collect all the increments for each ISM sample.
- Moved to the next increment location and continued until all increments in that sampling unit were collected. Once all increments had been collected, the soil was composited and thoroughly mixed in the plastic bag.
- Soil was placed into the appropriate glass jars.
- Labeled the sample containers and placed them on ice, completed the sample collection field sheet and a sample COC.
- Packed the cooler(s) for shipment to the analytical laboratory.

2.8.2.4 Sample Preservation and Storage

In the field, each sample container was marked with the sample identification number, date, time of sample collection and the sampler's initials. Sample containers for chemical analysis were placed in ice-filled coolers immediately following collection and stored at 4° Celsius prior to and during shipment. Sample containers were packaged to avoid breakage during transportation.

For each sample submitted to the analytical laboratory for analysis, an entry was made on a COC form. One COC form was completed for each cooler on each day of sampling. The information

recorded on the COC form included the sampling date and time, sample identification number, requested analyses and methods, and sampler's name(s).

COC forms were placed in a sealed plastic bag inside of the cooler with the samples. Upon receipt of the sample coolers, the laboratory verified the custody and condition of the samples.

2.8.2.5 Soil Sample Analyses

Each ISM soil sample collected from the low-density MEC and buffer area grids were submitted to Agricultural Priority Pollutants Laboratory, Inc. for chemical analysis for explosives (Method 8330B) and TAL metals (USEPA Method 6010B/6020A/7471B). A list of samples collected and analyses completed is presented in **Table 3-6**.

2.8.2.6 Quality Assurance/Quality Control (QA/QC)

Field QA/QC samples were collected to help identify potential sources of external sample contamination and to evaluate potential error introduced by sample collection and handling. Field QC can also provide insights into matrix homogeneity and uncertainty. All QA/QC samples were labeled with identification numbers and sent to the laboratory with the investigative samples for analyses.

Replicate Samples

Replicate samples (a minimum of two replicates per primary incremental sample) were collected at the same time as the initial sample and from the same sampling unit. The replicate soil containers were handled in the same manner as the primary samples. The replicate samples were assigned QA/QC identification numbers, stored in an iced cooler, and shipped to the laboratory on the day they were collected. Replicate samples were analyzed for the same parameters as the primary samples. Replicate samples were blind to the laboratory.

Matrix Spike and Matrix Spike Duplicates (MS/MSD)

The matrix sample, MS, and MSD data were used to evaluate the recovery of the analyte from the matrix (i.e., bias) and evaluate the reproducibility of the analyte in the MS/MSD (i.e., precision). Samples designated for MS/MSD analyses were identified on the COC form and on the sample containers. The laboratory used soil from the processed incremental samples for the MS/MSD. MS/MSD samples were collected from five percent of the total sample locations.

2.8.3 Buffer Area Grid Incremental and Discrete Soil Sampling Procedures

The Buffer Area grids that were sampled are shown on **Figure 2-2**. ISM and collocated discrete samples collected from the Buffer Area grids were obtained in the same manner as the sampling completed within the low-density area grids described in **Section 2.8.2**. In accordance with the Final Work Plan, the ISM samples were analyzed for explosives and metals, and the collocated discrete samples (centrally located within each sampled grid) were analyzed for VOCs; SVOCs;

NDMA; PCBs; and nitrate, cyanide, dioxins/furans, and perchlorate. Discrete soil sampling procedures are described in the following subsections.

2.8.3.1 Sampling Equipment

Soil was collected using disposable tools, including plastic disposable hand trowels, plastic bags, disposable plastic scoops, Terra Core® Samplers (for VOCs) and glass jars for analytical samples. Sample volumes, container types, and preservation requirements were followed per specific method requirements in accordance with USEPA SW-846.

2.8.3.2 Sample Identification

Samples collected during site activities were assigned discrete sample identification numbers. Each sample is identified by a unique code that indicates the parcel number, site identifier, matrix, and sample location identifier. The sample parcel number is P3 and the site identifier is "IF" for Inner Fence. The source of the sample IDs will incorporate the grid type of "BA" for buffer area and the grid ID.

An example of the sample ID code for the first soil sample collected from within Inner Fence, buffer area grid F10 would be P3IF-BA-GRID-F10. MS/MSD samples are given the same sample ID as the analytical sample but have "MS/MSD" written on the label. Field replicates samples are blind samples to the laboratory and are given a unique sample ID. Field duplicate samples had "500" added to the sample number to signify it is a duplicate sample.

2.8.3.3 Soil Sample Analyses

Each discrete soil sample collected from the buffer area grids were submitted to Agricultural Priority Pollutants Laboratory, Inc. for chemical analysis for VOCs (Method 8260B), semi-volatile organic compounds (SVOCs) (Method 8270D), NDMA (Method 8270 SIM), polychlorinated biphenyls (PCBs) (Method 8082A), nitrate (Method 9056A), cyanide (Method 9014), dioxins/furans (Method 8290), and perchlorate (Method 6850).

2.8.3.4 Soil Sample Collection

The following procedures were used to collect discrete soil samples:

- The UXO Technician cleared each sampling location immediately prior to sampling and offset the sample location as necessary to avoid any metallic anomalies in accordance with EM 385-1-97.
- Removed soil from the sampling location with a disposable plastic hand trowel until the sampling depth of 0.5 feet was reached.
- Collected the discrete soil for VOCs using the Terra Core® sampler from the ground. Filled 40 milliliter volatile organic analysis vials approximately with 5-grams of soil.

- Collected a discrete soil sample for all other parameters with a disposable plastic hand trowel and placed the soil in a disposable plastic bag.
- Composited the soil by mixing the soil in the plastic bag and then filled the jars for the specified analyses (**Table 3-6**).
- Labeled the sample containers and placed on ice, completed the sample collection field sheet and the sample COC, and packed the cooler(s) for shipment.

2.8.3.5 Sample Preservation and Storage

Sample preservation and storage for discrete samples followed the same procedure described for incremental samples (**Section 2.8.2.5**).

2.8.3.6 Quality Assurance/Quality Control

Field QA/QC samples are designed to help identify potential sources of external sample contamination and to evaluate potential error introduced by sample collection and handling. QA/QC samples for VOCs were collected using Terra Core® samplers. After VOC samples were collected, soil for the remaining analytes were mixed in a plastic bag and the appropriate jars were filled. A list of analytes can be found in **Table 3-6**. All QA/QC samples were labeled with QA/QC identification numbers and sent to the laboratory with the other samples for analyses.

Duplicate Samples

Duplicate samples were samples collected to assess precision of sampling and analysis. A duplicate sample was collected at the same time as the initial sample from ten percent of the total sample locations. The duplicate soil containers were handled in the same manner as the primary sample. The duplicate sample was assigned a QA/QC identification number, stored in an iced cooler, and shipped to the laboratory on the day it was collected. Duplicate samples were collected for all parameters. With the exception of duplicate samples collected using Terra Core® samplers (i.e., for VOC analyses), discrete soil samples were divided evenly, mixed in a plastic bag, and the appropriate jars were filled and submitted to the analytical laboratory. The Terra Core® VOC samples were not mixed. Duplicate samples were blind to the laboratory.

Matrix Spike and Matrix Spike Duplicates

MS/MSDs are used to assess the potential for matrix effects. Samples were designated for MS/MSD analysis on the COC form and on the bottles. MS/MSD samples were collected from five percent of the total sample locations.

2.9 FIELDWORK DOCUMENTATION

Fieldwork documentation including Daily Site Reports, Daily Quality Control Reports, and Forms 6048 is included in **Appendix A**.

3.1 MEC REMOVAL ACTION RESULTS

The subsurface RA of the IF began on August 28, 2017, and ceased in December 2020 due to concerns for personnel safety. The anomaly densities encountered were determined to be too high to safely identify and manually resolve as single point anomalies. It was concluded that the anomaly densities would continue to increase as the RA moved closer to the HWMU and the remainder of the IF subsurface RA, therefore, required alternative methods to complete.

The subsurface RA and subsurface removal operations were completed within 721 total grids within the IF. The removal grid locations and ID numbers are presented on **Figure 2-1** and listed in **Table 3-1** along with grid numbers and sizes. Over 1.4 million anomalies were investigated and over 338,8000 pounds of MD was recovered from these grids. **Table 3-2** presents the number of anomalies investigated and the weights of MD recovered by grid. **Figure 3-1** presents a color-coded anomaly density map and **Figure 3-2** presents a color-coded weight of MD map by grid. The figures demonstrate how anomaly densities and MD weights were increasing as the work progressed toward the HWMU.

A total of 16,578 MEC items were identified and recovered from the IF grids where manual RA activities were successfully completed as discussed in **Sections 2.4.1** and **6**. **Table 3-3** presents a summary of the MEC types recovered, including nomenclature and quantity. **Figure 3-3** shows the overall distribution of the MEC items recovered. The majority of MEC items recovered were point detonating (PD) and base detonating (BD) fuzes and 37 mm and 40 mm projectiles recovered from shallow depths of less than 12 inches. These four item types accounted for nearly 85 percent of the MEC recovered from the IF. The deepest MEC item recovered during IF subsurface removal operations (i.e., maximum depth of detection) was a 75mm HE projectile recovered from 22 inches bgs.

Table 3-4 presents a more comprehensive summary of the MEC items recovered by date and includes MEC item descriptions, munition types, quantities, depths of recovery, fuzing conditions, grid identifications (i.e., where the items were recovered), status of disposal, and the dates that the items were destroyed.

MEC items that were identified as unacceptable to move during the MPPEH inspection process were detonated in place as described in **Section 2.6**. **Table 3-5** lists the MEC items that were detonated in place, including dates of destruction, the NEWs of the demolition events (including the NEW of the donor explosives), and the destruction location coordinates. **Figure 3-4** shows each BIP MEC disposal location.

3.2 CHARACTERIZATION SOIL SAMPLING RESULTS

Following completion of the MEC removal and disposal activities summarized in **Section 3.1**, ISM soil samples were collected from 94 low-density area grids and ISM and discrete samples were collected from 76 buffer area grids. As detailed in **Section 2.8.2**, incremental samples were collected from both the low-density and buffer area grids and were analyzed for explosives and

metals. Additional discrete samples were also collected from the buffer area grids and analyzed for VOCs, SVOCs, NDMA, PCBs, perchlorate, dioxins/furans, cyanide, and nitrate. **Table 3-6** presents a sample summary for the low density and buffer area grids, including sample IDs, sampling dates and the laboratory analyses completed for each sample.

The analytical results are presented in **Appendix B** and the laboratory data and associated validation reports are presented in **Appendix C**. **Table 3-7** includes a summary of detected analyte concentrations (i.e., only one analytical result for arsenic) that exceeded the applicable human health SSLs detailed in **Section 4.1.3** (i.e., Residential SSL Cancer Endpoints and Residential Noncancer Endpoints). **Table 3-7** also shows multiple analytical results, specific to Dibenz[a,h]anthracene and n-Nitrosodimethylamine, where the limit of detection (LOD) exceeded the SSL for nondetect results as discussed in **Section 4.1.8**. The IF soil analytical results were not initially compared to preliminary Ecological SSLs, because the ecological SSLs were established as part of the tiered/phased Ecological Risk Assessment approach completed for the analytical data in accordance with NMED's *Risk Assessment Guidance for Site Investigations and Remediation, Volume 2, Soil Screening Guidance for Ecological Risk Assessments* (NMED 2017) as detailed throughout **Section 5** of the Report. The detailed evaluation of human health risks are detailed in **Section 4**.

3.3 CHEMICAL DATA USABILITY

Prior to use in the human health and ecological risk assessment, all site data were validated and qualified following the Quality Assurance/Quality Control (QA/QC) procedures described in the work plan (AECOM 2021). Data of insufficient quality based on QA/QC criteria were rejected at this point and not used. Sample results were assigned appropriate qualifiers at this stage:

- Data were considered usable for risk assessment purposes if 1) they were not qualified or 2) were estimated (J qualified).
- Data were not used if rejected (R qualified) or if nondetect (U qualified) in the field sample based on their presence in corresponding laboratory or field blanks. Other nondetect data for chemicals detected at least once in a media of concern were considered useable in the risk assessments for the calculation of exposure concentrations (ECs).
- Additionally, samples collected for QA/QC purposes (e.g., matrix spike/matrix spike duplicate) were used in the risk assessments.
- Nondetect results for dioxins and furans were not included in the calculation of the TEQs.
- For duplicates, the higher of the parent or duplicate results was used in the risk assessments.

Sample analytical results were also evaluated and screened for usability in the risk assessments using the USEPA guidance in the Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (USEPA 1989) and in the Guidance for Data Usability in Risk Assessment (USEPA 1990a).

Notes:

[1] NEW includes BIP item and donor explosives

* Highlighted yellow are from USACE requested BIPS

NEW - Net Explosive Weight

lbs - pounds

BIP - blown-in-place

4.1 HUMAN HEALTH RISK SCREEN APPROACH

This section describes the general approach used to complete the human health risk screen for the IF of Parcel 3.

4.1.1 Conceptual Site Model (CSM)

One of the first steps in formulating a risk screening for a site is developing a conceptual model of the site that identifies relevant exposure pathways and exposure scenarios. The updated CSM for the IF is discussed below and presented in **Figure 4-1**. As discussed in **Sections 2.4.1** and **3**, because multiple IF grids were excluded (i.e., to safety concerns associated with elevated anomaly densities in grids near the HWMU) from the manual removal operations completed, the updated CSM only applies to areas/grids within the IF where RA activities were successfully completed. As discussed in **Section 6**, additional remedial actions and/or land use controls may be warranted for IF grids/areas where RA activities were not completed, and possibly for depths up to 12 feet bgs where MEC could still be present (not anticipated) based on historical data for the Site.

FWDA's primary mission was to receive, store, maintain, and ship explosives and military munitions, as well as disassemble and dispose of unserviceable or obsolete explosives and other military munitions. The HWMU was where all detonations and burns of explosives and munitions occurred. Based on the release mechanism and conditions within the IF (i.e., dispersion of MEC from OB/OD activities at the HWMU resulting in surface area releases) and the results of the MEC RA (recovered MEC was at or just below the surface), the primary environmental medium impacted was surface soil. Although no subsurface sources of MEC (i.e., deeper than 22 inches bgs) were identified within the manually excavated grids of the IF, as discussed in **Sections 2.4.1** and **6**, based on historical accounts of MEC potentially deposited within the IF to depths up to 12 feet bgs, a remnant subsurface MEC exposure pathway cannot be completely discounted (i.e., for deeper MEC and associated MC). Although unlikely, subsurface soil could also be impacted by leaching and infiltration from associated remnant subsurface MC soil sources. Additionally, if volatile compounds leach to subsurface soil, then the vapor intrusion pathway would be potentially complete (not anticipated).

Sample results from work completed (both historically and currently) at the HWMU indicate that VOCs are infrequently detected and detected at low concentrations in the source area. Remediation work has been occurring at the adjacent HWMU since 2012 (with significantly deeper depths and higher densities of deposited MEC). Analytical results from these activities have indicated very little chemical contamination within the HWMU where significant detonation activities historically occurred (unlike within the IF Area). Although more than 3,250 soil samples have been collected to depths up to 25 feet bgs at the HWMU, less than 100 samples contained MC above their SSLs, indicating that subsurface contamination is even less likely to be a concern for the low density IF area addressed by this Report. However, as shown on **Figure 4-1**, subsurface exposure pathways cannot be completely discounted for the IF based on historical accounts noting that residual MEC could still be present to depths up to 12 feet bgs.

Currently, there is no one living or working within the IF. Additionally, there are no buildings, including commercial/industrial buildings or development within the IF. The area is surrounded by a security fence with locked gates. The fence and gates are checked annually to make sure they still restrict access to the site. Future land use for the IF is anticipated to remain as idle land within a secured fence; therefore, no future human exposure is expected for this site. If the anticipated future land use was to change to residential or commercial use, then residents, industrial workers, and construction workers would be potential future receptors.

Three groups of human receptors were identified as potentially applicable to the site: industrial/occupational workers, residents, and construction workers. NMED Risk Assessment Guidance (2022) indicates that residential and construction receptors have the potential to be exposed to both surface and subsurface soil (0 to 10 feet bgs). Industrial workers have the potential to be exposed to surface soil (0 – 1-foot bgs). As discussed above, based upon the release mechanisms, the primary exposure medium for the IF is surface soil (0 to 1-foot bgs). Therefore, the IF samples were collected from 0-1 foot beneath MEC items after they were removed.

Potentially complete surface soil exposure pathways are provided for each potential future receptor population.

- industrial/occupational worker (incidental ingestion of soil, dermal contact with soil, inhalation of airborne soil particulates and volatile emissions);
- resident (incidental ingestion of soil, dermal contact with soil, inhalation of airborne soil particulates and volatile emissions, and beef ingestion); and,
- construction worker (incidental ingestion of soil, dermal contact with soil, inhalation of airborne soil particulates and volatile emissions).

There are no permanent surface water bodies within the IF; therefore, the surface water exposure pathways were considered incomplete. Groundwater within the IF is being addressed as part of a separate investigation and not addressed in this document.

For sampling purposes, the IF was divided into the Buffer Area and the Low-Density Area based on the density of MEC. The Buffer Area is immediately bounding the HWMU/high-density MEC area. The Low-Density Area is adjacent to the Buffer Area. The sampling convention was retained through the evaluation of risk for consistency. Both the Low-Density and Buffer areas were comprised of multiple 100-foot x 100-foot grids which were individually sampled for MC. The grid size represents a more likely exposure area than the larger Buffer Area and Low-Density Area and is like a residential lot size.

4.1.2 Comparison with Background

All metals data for the Inner Fence was collected using incremental sample methodology. The background data available for FWDA is based on discrete samples; therefore, it was not used for a quantitative comparison with incremental samples. For the Inner Fence risk assessment, all

detected metals were included in the quantitative assessment of risk. If any metal was shown to be a risk driver, a qualitative assessment of the metal concentration using the FWDA background data (Shaw 2010), the 2012 background study (USACE 2013), the December 18, 2013 NMED letter (NMED 2013), and United States Geographical Society (USGS) metals studies (Shacklette, et al. 1984, Smith, et al. 2013) was completed for that metal to determine if site concentrations were consistent with background levels. Qualitative discussions are provided in **Section 4.2** as appropriate.

4.1.2.1 FWDA Background Studies

The FWDA background study (Shaw 2010) included 124 samples. Rigorous statistical tests were performed on these data including an evaluation of outliers. Based on the large data set and the rigorous statistical testing, the 2010 Shaw background study provides an unbiased, adequate, and reasonable representation of background conditions at FWDA.

In accordance with the December 18, 2013, NMED letter, if the arsenic background value of 5.6 mg/kg is exceeded then the result was compared to the background study range of 0.2 - 11.2 mg/kg.

4.1.2.2 USGS Metals Studies

The USGS 1894 *Element concentrations in soils and other surficial materials of the conterminous United States* (Shacklette et al. 1984) included soil or other regolith samples collected at depth of approximately 20 centimeters (8 inches) from locations about 80 kilometers (12 miles) apart, throughout the conterminous United States. In this manner, 1,318 sampling sites were chosen, and the results of the sample analyses for 50 elements were plotted on maps. The arithmetic and geometric mean, the geometric deviation, and a histogram showing frequencies of analytical values were provided for 47 elements. The study found regional geographical differences for metals, including a greater abundance of heavy metals in the western United States.

The *Geochemical and Mineralogical Data for Soils of the Conterminous United States* study (Smith, et al. 2013) began in 2007. The study involved a low-density (1 site per 1,600 square kilometers [995 square miles], 4,857 sites) geochemical and mineralogical survey of soils of the conterminous United States as part of the North American Soil Geochemical Landscapes Project. Sampling and analytical protocols were developed at a workshop in 2003, and pilot studies were conducted from 2004 to 2007 to test and refine these recommended protocols. The final sampling protocol for the national-scale survey included, at each site, a sample from a depth of 0 to 5 centimeters (2 inches), a composite of the soil A horizon, and a deeper sample from the soil C horizon or, if the top of the C horizon was at a depth greater than 1 meter (39 inches), from a depth of approximately 80–100 centimeters (30 inches – 39 inches).

4.1.3 Soil Screening Levels

Screening values used include NMED SSLs for residential, industrial/occupational, and construction worker land use scenarios (NMED 2022, or most current version). If an NMED SSL was not available for an analyte, the most current USEPA RSL (USEPA 2024) was used for that analyte. Carcinogenic RSLs were adjusted to a risk of 1.0E-05, consistent with NMED SSLs. Residential soil RSLs were selected for resident. Industrial soil RSLs were selected for the industrial/occupational worker. USEPA RSLs do not provide a construction worker RSL; therefore, a construction worker SSL was calculated using NMED (2022) construction worker exposure parameters.

The potentially complete soil exposure pathways were evaluated for potential cancer risks and non-cancer hazards through a risk-based screening process and calculation of cumulative risks as outlined below. Risk-based screenings and cumulative risk calculations were completed in accordance with the 2022 NMED risk assessment guidance. Additionally, in accordance with the 2022 NMED risk assessment guidance, non-cancer hazard refinements (e.g., target organ assessments) were used when non-cancer hazards greater than 1.0 were identified for an individual grid. Risk refinement is further discussed in **Section 4.1.8.**

4.1.4 Target Risk Levels

NMED guidance states SSLs are based on 1.0E-05 (1 in 100,000) target excess cancer risk or a target non-cancer hazard quotient of 1.0 for noncarcinogens (NMED 2022). Exceeding NMED SSLs means that further evaluation of chemical concentrations and exposure assumptions may be warranted.

4.1.5 Soil Exposure Intervals

The IF was impacted by kickout from detonation activities in the HWMU; therefore, surface soil was considered the primary medium of concern and the entire data set was used to evaluate potential risks for the IF, resulting in an exposure interval for all receptors (residents, construction workers, and industrial/occupational worker) of 0 to 1 foot (ft) bgs. As discussed in **Section 2.4.1**, because the MEC items manually removed from the completed IF grids were typically recovered from depths of 12 inches or less, subsurface MEC and associated MC exposure pathways were considered insignificant during the collection of RA soil samples and the associated RA risk assessment. However, as shown on **Figure 4-1**, and further discussed in **Section 6**, remnant subsurface exposure pathways (i.e., based on historical accounts of MEC deposited to depths up to 12 feet bgs within the IF Area), cannot be completely discounted for the site, even within the completed RA grids.

4.1.6 Screening Evaluation Exposure Concentrations

For IF discrete sample data sets, the exposure concentration used in the screening evaluation was the detected concentration for each analyte in each grid collected. For IS samples, the exposure concentration used in the screening was the maximum detected concentration of the replicate

samples in each grid collected. These exposure concentrations were used for both the comparison to NMED SSLs and the calculation of cumulative cancer risks and non-cancer hazards.

4.1.7 Screening Evaluation

Consistent with the guidance, screening was performed by directly comparing the concentration of each chemical detected at each sample location with NMED SSLs (NMED 2022) to identify which chemicals, if any, exceed their SSL. The screenings are provided in **Appendix D.1**. No chemicals were eliminated from the risk evaluation based on this step. All detected compounds were included in the calculation of cumulative risk.

4.1.8 Calculation of Cumulative Human Health Risk

NMED guidance indicates that the potential cumulative risks and hazards should be evaluated in the screening evaluation to conclude whether further evaluation may be necessary. Cumulative cancer risks and non-cancer hazards were calculated regardless of whether or not any detected chemical within a grid exceeded its SSL during the screening evaluation. This is consistent with NMED guidance (NMED 2022). Cumulative screening cancer risks and non-cancer hazards were calculated for each grid as follows:

- Site Screening Cancer Risk = (C1/SSL1 + C2/SSL2 + ……Cn/SSLn) x 1.0E-05
- Site Screening Non-cancer Hazard Index = (C1/SSL1 + C2/SSL2 + ……Cn/SSLn) x 1
- Where:

  C1...Cn = Screening exposure concentration for chemical “1” to chemical “n”.

  SSL1…SSLn = Soil screening level for chemical “1” to chemical “n” based on an SSL carcinogenic risk of 1.0E-05 or noncarcinogenic hazard of 1.0. Site risks less than the NMED target cancer level of 1.0E-05 and non-cancer hazard indices less than the NMED target level of 1.0 indicate that concentrations at the site are unlikely to result in adverse health impacts.

It is important to note that the HI is not linear. An HI of 100 does not mean the chances of noncancer health effects are 100 times more likely to occur, or that effects are likely to be more severe than an HI of 1.0. Rather, HIs greater than 1.0 simply indicate that non-cancer health effects are more likely to occur.

Nondetect results were compared to SSLs to assure that the detection limit (DL)/LOD/limit of quantitation (LOQ) were adequate to be detected at SSL concentrations. Historically at FWDA, only two compounds (dibenz(a,h)anthracene and n-nitroso-dimethylamine) have had detection levels that were too high to reach residential SSL levels. However, neither of these two compounds are known or suspected to have been used at FWDA. Nondetect results were not included in the calculation of cumulative cancer risks or non-cancer hazards for IF grids.

4.1.9 Risk Refinement

In accordance with NMED risk guidance (NMED 2022), if the non-cancer hazard index was greater than 1.0, for an individual grid, the grid underwent further, site-specific evaluation. This evaluation included a target organ/system assessment for chemicals with a noncarcinogenic endpoint to determine if noncarcinogenic effects are additive. The process involved calculating non-cancer hazard indices for each target organ or system and assessing whether or not the non-cancer hazard index for an organ or organ system exceeded 1.0. If no target organ/system hazard index exceeded 1.0, then the grid concentrations were not considered to pose any health issues for the receptor scenario being evaluated. No risk refinement of exposure concentrations was completed for any grid based on a noncancer hazard greater than 1.0. The specific target organ/system assessments are discussed in **Section 4.2**.

For excess cancer risks greater than 1.0E-05, the risk refinement consisted of the calculation of a 95 percent (%) upper confidence limit (UCL) concentration for the ISM samples (ITRC 2012). No exposure concentration refinement was completed for discrete samples because only one discrete sample was collected per grid. The specific exposure concentration refinements are discussed in **Section 4.2**. Nondetect data was used in the calculation of 95% UCLs ISM samples by including one-half the DL for each nondetect ISM result.

4.1.10 Dioxins/Furans

Toxicity data for the dioxin and furan congeners were assessed using the 2005 World Health Organization's toxicity equivalency factors (TEF) (Van den berg, et al 2006) as summarized in the NMED guidance (NMED 2022, Table 2-1). The TEF associated with each congener was applied to the maximum detected concentration of that congener. The summed adjusted values, or toxicity equivalent (TEQ) was compared to the NMED SSL for 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). A TEQ was calculated for each grid in both the low-density area and buffer area using the maximum detected concentration from each set of replicate samples. For nondetect results, the TEQ calculation used the lowest DL from the replicate samples. The TEQs are shown in the risk screening tables in **Appendix D.1**.

4.1.11 Evaluation of Lead Concentrations

Exposure to lead can result in neurotoxic and developmental effects. The primary receptors of concern are children, whose nervous systems are still undergoing development and who also exhibit behavioral tendencies that increase their likelihood of exposure (e.g., pica). These effects may occur at exposures so low they may be considered to have no threshold and are evaluated based on a blood lead level (rather than the external dose as reflected in the reference dose/reference concentration methodology). Therefore, the risk evaluation and toxicological approach used by USEPA and other agencies for lead is unique from other chemicals. For residential exposures, USEPA recommends the Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children for setting site-specific preliminary risk-based remediation goals. The adult lead exposure model (ALM) is the model currently used by USEPA to evaluate adult exposures in the workplace and is based on a pregnant mother's capacity to contribute to fetal

blood lead levels. The models for lead back-calculate to a soil concentration that would not exceed an estimated blood-lead concentration of 5 micrograms per deciliter. The NMED lead SSL for residential exposure is 200 mg/kg. The NMED lead SSL for the industrial/occupational exposure is 8.00E+02 mg/kg. Non-cancer hazard quotients are not calculated for lead because there is no established threshold value. For screening, the maximum detected concentration was presented simply as a comparison with the receptor-specific SSL. Additional evaluation using the lead models and risk refinement were not completed for lead because all the detected maximum concentrations were below the residential SSL (200 mg/kg) and the industrial/occupational SSL (800 mg/kg).

4.1.12 Vapor Intrusion Risks

Volatile organics having a Henry's Law constant greater than 1.0E-05 atmospheres–cubic meter/per mole (atm-m^3/mole) and a molecular weight less than 200 grams per mole are considered relevant to evaluation of the vapor intrusion pathway (NMED 2022). Currently, there are no buildings located within the IF; therefore, the current vapor intrusion pathway is considered incomplete. Vapor intrusion represents a potentially complete pathway for future receptors if a building was constructed in the area and VOC emissions become concentrated in indoor spaces. Sample results from work currently being completed at the HWMU indicate that VOCs are not detected at high concentrations (above SSLs) as a result of HWMU activities (AECOM 2024). Because the IF was impacted by kickout from the HWMU, it is expected that VOC concentrations in the IF would be lower than in the HWMU (the source area). Therefore, in accordance with Section 2.5 of the NMED risk guidance (NMED 2022), a qualitative assessment of potential vapor intrusion risk was completed and included in **Section 4.2.3** Uncertainties.

4.1.13 Beef Ingestion

NMED risk guidance (NMED 2022, Section 2.6) indicates two acres as the size of parcel requiring evaluation of the beef ingestion pathway. The IF in its entirety could provide enough land surface for grazing purposes. Additionally, grazing is a viable future land use for the area.

Therefore, in accordance with NMED risk guidance (NMED 2022), a qualitative assessment of ingestion of beef from cattle grazing on the IF was completed and included in **Section 4.2.3** Uncertainties.

4.1.14 Soil to Groundwater Migration

The soil to groundwater migration pathway was evaluated by comparing the maximum detected concentration for each chemical to available NMED soil to groundwater migration SSLs. If no SSL was available from NMED the chemical was considered to have no standard available. The low density and buffer areas were evaluated separately in **Tables 4-4** and **4-7**, respectively. Chemicals without soil-to-groundwater screening levels are noted in the tables.

4.1.15 Uncertainties

There are several sources of uncertainties associated with a human health risk screening. **Section 4.2.**3 presents and addresses the uncertainties encountered during the risk screening process.

4.2 HUMAN HEALTH RISK SCREEN RESULTS

This section presents the results of the risk screening for the IF of FWDA.

4.2.1 Low Density Grids

A total of 94 grids were sampled using incremental sampling for explosives and metals in the low-density area. These grids were evaluated individually for human health risks using the maximum detected concentration for each chemical from the replicate samples. None of the low density grids posed unacceptable cancer risks or adverse health effects for the industrial worker scenario. Several grids showed potentially unacceptable cancer risks (>1.0E-05) or adverse health effects (HQ/HI greater than 1.0) for residents and/or construction workers. **Tables 4-1** and **4-2** list all the low density grids with the potential to pose unacceptable cancer risks or adverse health effects for the residential and construction worker scenarios. The primary contributors for all these grids were metals, specifically aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium. **Table 4-3** presents the background metals data from FWDA and USGS metal reference studies (Shaw 2010, USGS 2013, respectively) and the low density and buffer area grid metals data. Risk refinements based on target organ/system assessments and a discussion of background were completed for these grids and are discussed below. All the low density individual grid 95% UCLs were greater than the maximum detected concentration of the replicate samples. Therefore, the 95% UCLs were not used in the risk refinements for hazard indices greater than 1.0.

Forty-eight low density grids had hazard indices greater than 1.0 for the residential scenario and 15 low density grids had hazard indices greater than 1.0 for the construction worker scenario (see **Table 4-1**). The primary contributors for all these grids were metals (aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium). The target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0. Therefore, these grids were considered to pose no unacceptable adverse health effects to residents or construction workers.

Seventy-seven low density grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese resulted in hazard greater than 1.0 for the construction worker scenario (see **Table 4-2**). Therefore, these grids may pose unacceptable adverse health effects for construction workers. Based on qualitative evaluation with background, **Table 4-3** shows low density grid manganese concentrations ranging from 190 mg/kg to 930 mg/kg are within the FWDA background range of 37.7 mg/kg to 2,240 mg/kg and the USGS reference ranges (<2 mg/kg to 12,000 mg/kg). Therefore, manganese concentrations

in these low density grids may be naturally-occurring and not related to site activities and grid risk/hazards may been over estimated. However, as discussed in **Section 4.1.2**, because the available background data for metals at FWDA were obtained using discrete sampling approaches, these qualitative conclusions for the incremental sample results for metals are considered preliminary.

Grid AL39 had a cancer risk of 1.2E-05 for residents. The only contributor to excess cancer risk was arsenic. The maximum arsenic concentration (8.6 mg/kg) exceeded the qualitative background value of 5.6 mg/kg established for FWDA; however, it was within the FWDA background range of 0.2 mg/kg to 11.2 mg/kg and the USGS reference studies with maximum detected concentrations ranging from 97 mg/kg – 1,110 mg/kg. The arsenic concentrations in AL39 appear to be within qualitative background levels and may not be related to site activities. Therefore, the excess cancer risk associated with arsenic in Grid AL39 was considered to be potentially related to naturally occurring concentrations rather than site-related activities. However, as discussed in **Section 4.1.2**, because the available background data for metals at FWDA were obtained using discrete sampling approaches, these qualitative conclusions for the incremental sample results for metals are considered preliminary.

All lead concentrations from the low-density grids were below the NMED residential SSL (200 mg/kg); therefore, no further evaluation of lead concentrations was necessary.

Based on these results, potential excess cancer risks and noncancer hazards were below the target risk of 1.0E-05 and the hazard threshold of 1.0 for organic compounds. Therefore, there are no significant risks and no further evaluation of the current and future resident, site worker or construction worker scenarios is necessary for organic compounds. The individual grid human health risk screenings are provided in **Appendix D.1**.

The soil to groundwater migration pathway evaluation is provided in **Table 4-4**. The comparison showed the detected concentrations of 2-amino-4,6-dinitrotoluene (5 grids), 4-amino-2,6-dinitrotoluene (1 grid) and Tetryl (1 grid) exceeded the soil to groundwater migration SSLs. Therefore, explosives have the potential to impact groundwater in the vicinity of the associated grids. Additionally, detected concentrations of arsenic (1 grid), cobalt (multiple grids), and iron (all grids) exceeded the migration SSLs. The qualitative comparison of metals results to FWDA background levels and established naturally-occurring ranges from USGS indicated that the results were consistent with background/naturally-occurring ranges and may not be site-related. However, as discussed in **Section 4.1.2**, because the available background data for metals at FWDA were obtained using discrete sampling approaches, these qualitative conclusions for the incremental sample results for metals are considered preliminary.

The individual grid human health risk screening are provided in **Appendix D.1**.

4.2.2 Buffer Area Grids

A total of 76 grids were sampled using discrete sampling (VOCs, SVOCs, polychlorinated biphenyls, dioxins/furans, cyanide, perchlorate, nitrate) and incremental sampling (explosives

and metals) in the buffer area. These grids were evaluated individually for human health risks using the maximum detected concentration for each chemical from the discrete and incremental samples.

Excess cancer risks for all 76 grids were below the NMED target cancer risk of 1.0E-05. All industrial worker hazard indices were below 1.0. Several buffer area grids showed the potential for adverse health effects (HQ/HI greater than 1.0) for residents and/or construction workers. **Tables 4-5** and **4-6** list all the buffer area grids with the potential to pose unacceptable adverse health effects for the residential and construction worker scenarios. The primary contributors for all these grids were metals, specifically aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium. **Table 4-3** presents the background metals data from FWDA and USGS metal reference studies and the buffer area grid metals data. Risk refinements based on target organ/system assessments and a discussion of background were completed for these grids and are discussed below. All the buffer area individual grid 95% UCLs were greater than the maximum detected concentration of the replicate samples. Therefore, the 95% UCLs were not used in the risk refinements for hazard indices greater than 1.0.

Thirty-four buffer area grids had hazard indices greater than 1.0 for the residential scenario and 16 grids had hazard indices greater than 1.0 for the construction worker scenario (see **Table 4-5**). The primary contributors for all these grids were metals (aluminum, arsenic, barium, chromium, cobalt, iron, manganese, and/or thallium). The target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0. Therefore, these grids were considered to pose no unacceptable adverse health effects to residents or construction workers.

Thirty-five buffer area grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese resulted in hazard greater than 1.0 for the construction worker scenario (see **Table 4-6)**. Twenty buffer area grids had hazard indices greater than 1.0 due to manganese. Therefore, these grids may pose unacceptable adverse health effects for construction workers. Based on qualitative evaluation with background, **Table 4-3** shows buffer area grid aluminum concentrations ranging from 5,800 mg/kg to 33,000 mg/kg are within the USGS reference ranges (700 mg/kg to >10,000 mg/kg and 10,000 mg/kg to 60,000 mg/kg). Additionally, buffer area manganese concentrations ranging from 190 mg/kg to 790 mg/kg are within the FWDA background range of 37.7 mg/kg to 2,240 mg/kg and the USGS reference ranges (<2 mg/kg to 12,000 mg/kg). Therefore, aluminum and manganese concentrations in these buffer area grids may be naturally-occurring and may not be related to site activities and grid risk/hazards may have been over estimated. However, as discussed in **Section 4.1.2**, because the available background data for metals at FWDA were obtained using discrete sampling approaches, these qualitative conclusions for the incremental sample results for metals are considered preliminary.

All lead concentrations from the buffer area grids were below the NMED residential SSL (200 mg/kg); therefore, no further evaluation of lead concentrations was necessary.

Based on these results, the buffer area is unlikely to pose any unacceptable cancer risks or adverse health effects for current and future residents, site workers, or construction workers. The individual grid human health risk screens for the buffer are provided in **Appendix D.1**.

The soil to groundwater migration pathway evaluation for Buffer Area grids is provided in **Table 4-7**. One VOC (1,2-dibromo-3-chloropropane) had an LOD, both maximum and minimum, above its respective groundwater migration SSL. However, because laboratory technology was not available to detect this chemical at the level of its soil to groundwater SSL during completion of this IF RA, additional evaluation of the analyte will be completed during future groundwater sampling activities to be conducted, including the IF Area, during the on-going Parcel 3 Groundwater RCRA Facility Investigation (RFI) Supplemental Sampling as is further discussed in **Section 6**.

No SVOCS were detected at concentrations above their groundwater migration SSLs; however, several SVOCS had LODs, both maximum and minimum, above their groundwater migration SSLs. Several of these SVOCS are unable to be detected at concentrations as low as the SSLs and they have not been detected in any Inner Fence samples. Any potential impacts to groundwater in the vicinity of the grids would be dependent on the depth to groundwater and whether or not the compounds are actually present in soil.

The comparison showed the detected concentrations of 2-amino-4,6-dinitrotoluene (1 grid), 4-amino-2,6-dinitrotoluene (9 grids), RDX (1 grid), and Tetryl (1 grid) exceeded the soil to groundwater migration SSLs. Therefore, there is potential for groundwater to be impacted in the vicinity of these grids. Several explosives had LODs, both maximum and minimum, that exceeded the groundwater migration SSLs. Any potential impacts to groundwater in the vicinity of the grids would be dependent on the depth to groundwater and whether or not the compounds are actually present in soil below detectable levels. However, as discussed in **Section 6**, additional RFI groundwater sampling within the IF Area will be completed to further evaluate the potential migration of site contaminants from soil to groundwater at the site.

Table 4-7 shows two PCBs have LODs above their groundwater migration SSLs. While there is the potential for groundwater to be impacted by PCBs, no PCBs were detected in any Inner Fence soil samples.

Two metals were detected at concentrations above their groundwater migration SSLs: cobalt (10 grids) and iron (all grids). The qualitative assessment of metals to FWDA background levels and established naturally-occurring ranges from USGS indicated that these metals results may be within background/naturally-occurring ranges. However, as discussed in **Section 4.1.2**, because the available background data for metals at FWDA were obtained using discrete sampling approaches, the qualitative conclusions for the incremental sample results for metals are considered preliminary. Additional evaluation of IF Area metals concentrations and the potential for migration to groundwater will be completed during the on-going Parcel 3 Groundwater RFI Supplemental Sampling as discussed in **Section 6**.

4.2.3 Uncertainties Associated with the Human Health Risk Screening

There are several sources of uncertainties associated with a human health risk screening. These are discussed below.

General Risk Assessment Uncertainties

- Samples were analyzed using USEPA-approved procedures, and were subjected to USEPA data validation procedures, to assure that data were suitable for use in decision-making. However, sample analysis is subject to uncertainties associated with precision and accuracy, and detection of chemicals at low concentrations. Analytical precision and accuracy are evaluated through laboratory quality assurance programs that have been reviewed by project stakeholders. Uncertainties associated with precision and accuracy of analysis are generally random and may lead to over or underestimation of risks. These errors are typically of low magnitude and are unlikely to have a significant impact on the results of the risk assessment when compared to other sources of uncertainty in the risk assessment.
- It was assumed that samples collected were representative of the area to which various populations may be exposed. However, the collected samples may not be completely representative, due to biases in sampling and to random variability of samples. In addition, soils are not homogeneously distributed in the environment. Random variability of the media sampled may result in either an over or underestimation of actual chemical concentrations, and thus, site risks. VSP software was used to determine the quantity of samples required to statistically demonstrate if residual contamination poses a risk to receptors. VSP software supports the development of a defensible sampling plan based on statistical sampling theory and the statistical analysis of sample results to support confident decision making. Therefore, samples collected were considered to representative as possible and any remaining uncertainties are unlikely to significantly impact the results of the risk assessment.
- Chemical concentrations used to evaluate potential site risks are based on the available environmental soil. Environmental sampling is designed to identify and fully characterize the type and extent of contamination at a site. Therefore, environmental sampling is biased toward finding contamination and it is unlikely contaminant concentrations have been underestimated. Sampling software (VSP) was used to determine the sampling plan for the IF investigation to assure 95 percent confidence that at least 97 percent of the grids in the decision unit (low-density area) were acceptable (i.e., below SSLs). The use of this software minimized the uncertainties associated with the IF characterization activities. Additionally, every buffer area grid that could be safely sampled was sampled. Therefore, any uncertainties associated with contaminant concentrations in the IF have been minimized and would have no significant impact on the results of the risk assessment.
- Risk assessment is an uncertain process which requires both scientific data and science-based assumptions. Risk assessments are conducted to infer risks below the range of observable events in people and studies of laboratory animals. For example, regulatory agencies typically attempt to protect populations from exposure to doses of chemicals that may pose a cancer risk of one in one million or greater. It is virtually impossible to measure the impact of

a one-in-one-million cancer risk on a population where one-third of that population is already expected to be diagnosed with cancer, even in the absence of a particular chemical exposure (USEPA 1990b; 1992).

- This risk assessment evaluated the toxicity or risk associated with individual chemicals and then combined them to estimate risk as it related to chemical mixtures. However, simply adding risks ignores potential synergistic or antagonistic interactions, as well as differences in target organ specificities and differences in mechanisms of action that could lead to either underestimation or overestimation of total risk. The synergistic and antagonistic interactions and target organ specificities and mechanisms of action between chemicals is not fully understood; therefore, the overall impact on the risk assessment results cannot be assessed.
- The residential SSL assumes person is present 24 hours a day, 350 days per year for 26 years (noncancer) or 70 years (cancer). These are conservative assumptions. In today's culture, it is not uncommon for people to leave their homes on a regular basis for work, playdates, social engagements, errands, sporting events, etc. While the exposure assumptions for residents are likely to overestimate potential site risks for most future residents, the exposure assumptions are designed to be protective of the most conservative exposure scenarios. Therefore, while the risks for residents may have been overestimated for a typical residential scenario, it is not considered to be exaggerated beyond what potential future residential risks could be and are within acceptable levels.
- There are no residents, workers, or construction workers currently located at the IF. The IF is surrounded by a security fence with locked gates. The fence and gates are checked annually to make sure they are still restricting access to the site. Future land use for the IF is anticipated to remain as idle land within a secured fence; therefore, no future human exposure is expected for this site. Therefore, the exposure scenarios represent a major source of uncertainty which could overestimate actual site risks based on the projected future land use. If the anticipated future land use was to change to residential or commercial use, then residents, industrial workers, and construction workers would be potential future receptors and the estimated risks would be representative of potential future risks for those receptors.
- Maximum detected concentrations for discrete samples were used in the estimate of site risks. Generally, the use of maximum detected concentrations likely overestimates site risks because receptors are unlikely to spend the entire exposure duration and frequency assumed by the SSLs in contact with the maximum concentrations. The use of the VSP software to design the sampling plan minimized the uncertainty associated with sample concentrations and representation of the sampled areas. However, no samples were collected beneath MEC where the highest likelihood of residual contamination would be located. Therefore, site risks may have been underestimated.
- The currently accepted qualitative background study for FWDA (Shaw 2010) is comprised of discrete sample data. The metals data for the Inner Fence area was collected using ISM. For the human health risk screen, all detected metals were included in the quantitative calculation of site cancer risks and hazards. If metals posed a potential cancer risk or hazard, a qualitative assessment was made based on the comparison of the range of detected metals concentrations for the low density and buffer area to the FWDA detected range and USGS

metal reference ranges. No statistical population comparisons were completed due to difference in sampling methodologies between the site data and reference studies (i.e., discrete, ISM, composite). The FWDA background study (Shaw 2010) was comprised of 124 samples (including duplicates). The USGS reference studies (1984 and 2013) included over 1,300 samples (USGS 1984) and approximately 4,800 samples in each of three soil horizons. Metals detected within the range of the FWDA background and USGS ranges were considered to be potentially naturally-occurring. However, additional evaluation is planned for future RFI activities planned at the IF.

- USEPA cancer slope factors used to calculate SSLs are highly conservative estimates of dose-response relationships and probably likely result in a significant overstatement of actual cancer risk. Cancer slope factors are calculated using the 95% upper confidence limit (UCL) on a dose-response curve estimated by a linear mathematical model that extrapolates from short-term, high-dose animal exposures to long-term, low-dose human exposures. USEPA guidance states the cancer SFs are upper-bound estimates of potency.

- The following should be considered in order to interpret the significance of the cancer risk estimates. The National Oil and Hazardous Substances Pollution Contingency Plan (USEPA 1990b) states, "For known or suspected carcinogens, acceptable exposure levels are generally concentration levels that represent an excess upper-bound lifetime cancer risk to an individual of between 1E-04 and 1E-06." These values are equivalent to a 1 in 10,000 to 1 in 1,000,000 chance of getting cancer from the exposure. These risk levels are very low and would not be measurable or discernible (compared to the background cancer risk of approximately 1 in 3) in individuals or even in a large population. For example, a risk level of 1 in 10,000 (1E-04) would increase an individual's chance of getting cancer from the background risk of 1 in 3 to 1.0001 in 3. The Guidance on Risk Characterization for Risk Managers and Risk Assessors (USEPA 1992) concurs with the 1E-04 to 1E-06 target risk range.

- Surrogate compounds were used in the risk assessment. 1,3-Dichloropropene was used as a surrogate for 1,1-dichloropropene and cis- and trans-1,3-dichloropropene. 1,4-Dichlorobenzene was used as a surrogate for 1,3-dichlorobenzene. 1,2-Dichloropropane was used as a surrogate for 2,2-dichloropropane. Cumene was used as a surrogate for p-isopropyltoluene. 4-Nitroaniline was used as a surrogate for 3-nitroaniline. Pyrene was used as a surrogate for acenaphthylene and benzo(g,h,i)perylene. The use of surrogates during the screening phase may have resulted in a chemical being removed as a chemical of potential concern (COPC) based on the currently available screening criteria. In the future, criteria specific to that chemical may become available and indicate the surrogate used in this assessment was not protective and associated risks were underestimated. Similarly, future information could indicate that surrogate presents higher risks than the chemical specific toxicities. In this case, the site risks would have been overestimated and were thus protective.

Exposure Pathway Uncertainties

- Beef ingestion is a potentially complete pathway for the IF of FWDA. However, all chemicals detected in the Low Density area were below their residential SSLs, except for arsenic which resulted in an excess cancer risk of 12E-05. A qualitative assessment of background concentrations indicated that arsenic was likely present at naturally -occurring concentrations. Additionally, residential cumulative cancer risks and hazards did not pose any acceptable excess cancer risks or adverse health effects for the Low Density area. Similarly, in the Buffer Area, all detected chemicals were below their residential SSLs. Residential cumulative cancer risks and hazards did not pose any acceptable excess cancer risks or adverse health effects for the Buffer Area. Finally, **Table 4-8** shows that the maximum detected concentrations of metals did not exceed the screening values for the pronghorn antelope, a larger game receptor. Therefore, the beef ingestion pathway is considered to pose no unacceptable cancer risks or non-cancer hazards for future populations who might raise and eat cattle in the low-density and/or buffer area of the IF. It is important to note, however, that soil analytical/risk assessment results in nearby high anomaly/MEC density areas (e.g., adjacent HWMU grids) could have different results than this human health risk assessment.

- Vapor intrusion was not evaluated quantitatively in the risk screening for the IF. The data set for the IF was limited to shallow soils (3 feet bgs or shallower) because the IF was received kickout from the HWMU which impacted surface soils. Based on the risk screen completed, shallow soils show no apparent risk via the vapor intrusion pathway due to very low levels of volatile organic compounds. Low levels of VOCs are consistent with historical and current soil results from the HWMU. Vapor intrusion is generally dependent upon the shallowest groundwater layer and subsurface soil. These environmental media were not sampled as part of this investigation; therefore, vapor intrusion risk could not be evaluated quantitatively for the IF. Potential site risks may have been underestimated based on the inability to quantitatively assess the vapor intrusion pathway. Leaching and infiltration could lead to subsurface soil/shallow groundwater contamination; however, New Mexico is located in the arid southwest and receives limited rainfall. Volatile compounds were not widely or regularly detected in the Inner Fence area at concentrations exceeding groundwater migration SSLs. Although several volatile compounds had LODs above the groundwater migration SSLs, these chemicals were also not detected in any Inner Fence samples indicating they may not be present in Inner Fence soils. Therefore, any underestimation of risk would be considered minor and not impact the quantitative risks results for the IF. However, the migration to groundwater pathway will be further evaluated with additional groundwater sampling activities conducted within the IF Area during on-going Parcel 3 Groundwater RFI Supplemental Sampling as is further discussed in **Section 6**.

Data Uncertainties

- As documented in the NMED-approved Work Plan, VSP statistical sampling software was utilized to determine the quantity of samples required to statistically demonstrate whether or not residual contamination could pose a risk to receptors and reduce any uncertainties associated with the data obtained and evaluated for risk. VSP is an industry standard

software tool that supports the development of a defensible sampling plan based on statistical sampling theory and the statistical analysis of sample results to support confident decision making. The program was developed with the support of numerous government agencies (i.e., U.S. Department of Energy, USEPA, and DoD) to ensure that the right type, quality, and quantity of data are generated in support of remedial decision making. As detailed in **Section 2.8.1.1**, to reduce data uncertainty, the risk assessment for the analytical data generated relied on a VSP-based ISM and collocated discrete sample design for the RA-completed grids within the buffer and low-density areas of the IF.

TABLE 4-1

[1] These metals concentrations were presented on a percent by weight in the USACE 2013 document; therefore, the results were not used in this assessment.

[2] Western United States is defined as west of the 96th Meridian (USGS 1984). In the U.S., the 96th Meridian passes through Minnesota, Iowa, Nebraska, Kansas, Oklahoma, and Texas.

[3] The A Horizon was not specifically defined in the the USGS 2013 document.

[4] If the top of the soil C horizon was at a depth greater than 1 meter (39 inches), the sample was collected from a depth of approximately 80 - 100 centimeters (30 - 39 inches).

*As presented in USGS 1984.

Abbreviations and Acronyms

-- = no data presented in cited documents
% = percent
< = less than
BA =Buffer Area
cm = centimeter
FWDA = Fort Wingate Depot Activity
LD = Low Density Area
UCL = upper confidence limt
U.S. = United States
USGS = United States Geological Survey
UTL = upper tolerance limit

Notes:

[1] NMED = New Mexico Environment Department Screening Levels (NMED 2022, November update).

[2] Chromium screening value is for Total Chromium.

*A qualitative review of background and naturally-occurring levels shows that detected arsenic, cobalt, and iron concentrations may be naturally-occurring levels and may not be site related.

CAS = Chemical Abstracts Service

J = Estimated

mg/kg = milligrams per kilogram

N = no

NS = No Standard

SSL = soil screening level

U = Nondetect

Y = yes

Notes:

[s] = 1,3-Dichloropropene was used as a surrogate for 1,1-dichloropropene and cis- and trans-1,3-dichloropropene. 1,4-Dichlorobenzene was used as a surrogate for 1,3-dichlorobenzene. 1,2-Dichloropropane was used as a surrogate for 2,2-dichloropropane. For m,p-xylenes the lower value between m-xylene and p-xylene was used for the sum of the isomers. Cumene was used as a surrogate for p-isopropyltoluene. 4-Nitroaniline was used as a surrogate for 3-nitroaniline. Pyrene was used as a surrogate for acenaphthylene and benzo(g,h,i)perylene.

1) NMED = New Mexico Environment Department Screening Levels (NMED 2022, November update).

2) Toxicity data for the dioxin and furan congeners were assessed using the 2005 World Health Organization's (WHO) toxicity equivalency factors (TEF) (Van den berg, et al 2006). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the NMED cancer and non-cancer SSLs for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). (NMED 2022, November update).

3) Chromium screening value is for Total Chromium.

Dibenz(a,h)anthracene has an SSL above the DL and LOD but below the LOQ. However, this compound is not known to have been used at FWDA. Dibenzo(a,h)anthracene is a polycyclic aromatic hydrocarbon (PAH) with no commercial production or known use. It occurs as a component of coal tars, shale oils, and soots and has been detected in gasoline engine exhaust, coke oven emissions, cigarette smoke, charcoal broiled meats, vegetation near heavily travelled roads, and combustion sources. (If there was a detection between the DL and LOQ the lab would J qualify the result the substance might be there but at a higher degree of uncertainty. Results were U qualified to the LOD as non-detect per the DoD QSM.)

N-Nitrosodimethylamine has an SSL below the DL, LOD, and LOQ. However, this analyte is not suspected to have been used at Fort Wingate. N-nitrosodimethylamine was produced by industry only in small amounts for research.

According to Section 5.3 of the NMED RAG, November 2022 update, essential nutrients (calcium, chloride, magnesium, phosphorus, potassium, sodium) should be evaluated separately. "If the maximum detected concentration for the site is below the soil SSL, resulting in an HQ of less than one, then exposure is not likely to cause adverse effects to receptors, and the inorganic constituent may be eliminated from further evaluation in the risk assessments. The risks from essential nutrients may be discussed separately from the overall HI for noncarcinogens.

CAS = Chemical Abstracts Service

DL = Detection limit

J = Estimated

LOD = Limit of detection

LOQ = Limit of Quantitation

mg/kg = milligrams per kilogram

NS = No Standard

TEF = Toxicity Equivalency Factor

TEQ = Toxicity Equivalency Quotient

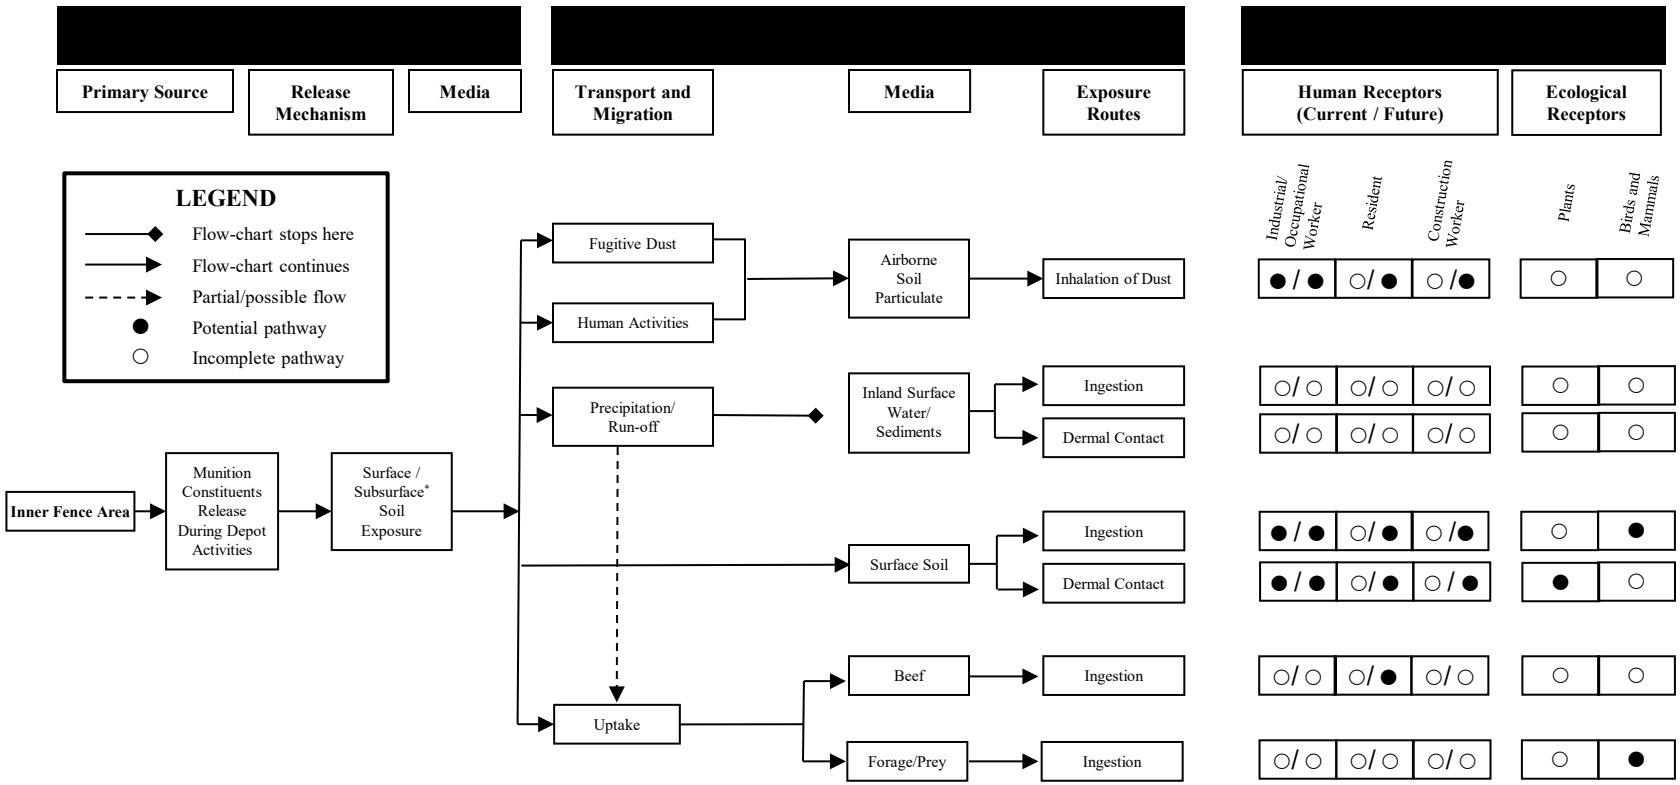
FIGURE 4-1
INNER FENCE AREA SITE CONCEPTUAL EXPOSURE MODEL
FORT WINGATE DEPOT ACTIVITY, McKINLEY COUNTY, NEW MEXICO



*Subsurface soil exposures to MC were considered minor pathways and were not specifically evaluated in the risk assessment because the release mechanism and historical HWMU data indicate subsurface soil is not a medium of concern for the Inner Fence area. However, as discussed in **Sections 2.4.1** and **6** a remnant subsurface exposure pathway (i.e., for MEC/associated MC at depths up to 12 feet bgs cannot be completely discounted, even within the completed RA grids). Vapor intrusion was considered a minor pathway and was not evaluated quantitatively in this risk assessment. Vapor intrusion is discussed qualitatively in **Section 4**.

5.1 ECOLOGICAL RISK SCREEN APPROACH

The ecological evaluation was conducted in general accordance with NMED's *Risk Assessment Guidance for Site Investigations and Remediation, Volume 2, Soil Screening Guidance for Ecological Risk Assessments* (NMED 2017). NMED methodology is divided into two phases for completing an ecological risk assessment:

- Phase I – Scoping and Screening Assessments
  - Scoping Assessment
  - Screening Level Ecological Risk Assessments (SLERA) (Tiers 1 and 2)
- Phase II – Site-Specific Assessments
  - Site-Specific Ecological Risk Assessment (Tier 3)

5.1.1 Scoping Assessment

The Scoping Assessment served as the initial information gathering and evaluation for the ecological risk assessment process. The Scoping Assessment consisted of the following steps:

- Compiled and Assessed Basic Site Information (a Site Assessment Checklist provided in NMED Guidance may be used)
- Conducted Site Visit
- Identified Preliminary Contaminants of Potential Ecological Concern
- Developed a Preliminary Conceptual Site Exposure Model. This is referred to as the Ecological Conceptual Exposure Model (ESCM) in this document
- Prepared a Scoping Assessment

The detailed Scoping Assessment is provided in **Section 5.2.1**. A Technical Decision Point at the conclusion of the Scoping Assessment concluded that further ecological investigation is warranted in a Tier 1 screening-level evaluation.

5.1.2 Tier 1 Screening-Level Ecological Risk Assessment Methodology

The scoping assessment indicated complete exposure pathways The Tier 1 SLERA is the next step. The Tier 1 SLERA uses information collected during the Scoping Assessment and contains the following:

- Characterization of the environmental setting, including current conditions and future land uses.
- Identification of known or likely chemicals of potential ecological concern (COPECs) based on site activities.

- Evaluation of the fate and transport pathways of COPECs to identify those that form a complete link from source to potential receptor.
- Identification of the environmental values to be protected (the assessment endpoints), particularly noting the presence or potential presence of protected species or habitats.
- Identification of the impacted media, complete exposure pathways, and exposure routes.
- Species likely to be impacted and selection of representative receptors.

Given the information compiled, the Tier 1 SLERA determined further evaluation is necessary based on:

- Assessment of the potential magnitude of exposure using the maximum detected concentration and conservative Tier 1 exposure assumptions.
- Identification of COPECs with the potential to cause adverse effects to ecological receptors based on conservative exposure assumptions and no-observed adverse effect level (NOAEL) toxicity reference values (TRVs).

Another Technical Decision Point followed the Tier 1 SLERA which determined further evaluation is warranted in a Tier 2 SLERA. Detailed results of the Tier 1 SLERA are presented in **Section 5.2.2**.

5.1.3 Tier 2 Screening-Level Ecological Risk Assessment Methodology

Less conservative methodologies were applied in Tier 2. A more reasonable representation of the exposure concentration was used expressed as the 95% UCL of the mean rather than the maximum detected concentration. For birds and mammals, exposure models using more representative estimates of receptor characteristics were employed (e.g., average body weight and ingestion estimates). In addition, NMED recommends a lowest-observed-adverse-effects level (LOAEL) TRV as a benchmark more representative of population risks than the NOAEL. Detailed results of the Tier 2 SLERA are presented in **Section 5.2.3**.

5.1.4 Tier 3 Ecological Risk Assessment Methodology

Tier 3 includes additional quantitative analyses (e.g., biota studies to evaluate impacts at the site) or corrective actions (e.g., removals). Tier 3 is not included in the scope of the current evaluation.

5.2 ECOLOGICAL RISK SCREEN RESULTS

The ecological risk screening approach was presented in **Section 5.1**. Detailed results are presented in the following subsections.

5.2.1 Scoping Assessment

As discussed previously, the Scoping Assessment serves as the initial information gathering and evaluation for the ecological risk assessment process.

5.2.1.1 Basic Site Information

An overview of the Site was provided in **Sections 1.3 through 1.6**. The focus of this section is on the environmental setting. The majority of this information was obtained from the *Final Resource Restoration Plan and Environmental Assessment for the Fort Wingate Depot Activity Site* (Navajo Nation, New Mexico Office of Natural Resources Trustee, US Department of Army, Zuni Tribe, 2024),

Because of the FWDA's location and the range of topographic elevations found at the site, the property provides suitable conditions to support three different life zones comprised of various cold desert and semiarid vegetative communities. These include the Upper Sonoran Life Zone, the Transition Life Zone, and the Montane Life Zone (ERM, 1997). The Transition Zone occurs in the higher elevations and the mountain slopes of the Zuni Mountains in the central and southern section of the FWDA. This zone forms a transitional area where the flora and fauna from the lower Upper Sonoran and the higher Montane Life Zones mix. The lower elevations of the Transition Life Zone are represented by open piñon-juniper forests, shrublands, and some grassland communities. The Montane Life Zone is restricted to the higher elevations of the Zuni Mountains along the southern third of the FWDA where ponderosa pine forests dominate (ERM, 1997). The IF lies within the Transition Life Zone.

Desert Scrubland and Piñon/Juniper Woodland occupy the majority of land area near FWDA (ERM, 1997). The desert shrubland community is primarily dominated by big sagebrush, fourwing saltbrush, golden rabbitbrush, and black greasewood. However, other shrub species such as dune broom, winterfat, broom snakeweed, Mormon tea, mock heather, antelope brush, and spineless horsebrush also occur interspersed among the dominant shrubs. The species in the herbaceous stratum of this community include western wheatgrass, ring muhly, wild oats, blue grama, alfileria, needle and thread, bottlebrush squirrel tail, and various forbs (NMSU, 2011).

The piñon/juniper woodland community is dominated by piñon and juniper trees usually less than 30 feet tall that have short, twisted trunks and wide, spreading crowns. This community is best characterized by its widely spaced, mixed stand of piñons and junipers that occur in dry and rocky or gravely terrain (NatureServe, 2023).

Specific species of pine and junipers that are located in this community include two needle piñon pine, one-seed juniper, and Utah juniper (NatureServe, 2023). The shrub stratum of this community is similar to species found in the desert scrubland community, and includes species such as big sagebrush, antelope brush, cliff rose, fourwing saltbrush, golden rabbitbrush, tomatillo, broom snakeweed, dune broom, Mormon tea, and shadscale. The species in the herbaceous stratum of this community included many of the same grasses and forbs found in the

desert scrubland and grassland communities. Additional flora in the herbaceous stratum include species such as cushion cactus and prickly pear cactus (NMSU, 2011).

5.2.1.2 Site Visit

Site visits were conducted in conjunction with site assessment and sampling activities. A Scoping Assessment Checklist is provided in **Appendix D.2**, Attachment A. Additional detail is provided in the following sections.

5.2.1.3 Special-Status Species and/or Environments

Consideration was given to the possible presence of threatened and endangered species as well as sensitive environments. There are no known National Parks or National Monuments, Wilderness Areas, Wildlife refuges, Nations Lakeshore Recreational Areas, designated game management areas, or other resources defined in NMED Guidance as sensitive environments, except as discussed below.

A report of threatened and endangered species for McKinley County was obtained from the Biota Information System of New Mexico (BISON-M) (**Appendix D.2**, Attachment 2). BISON-M contains accounts for all vertebrate and many invertebrate species that occur in New Mexico, including all threatened and endangered species (NMDGF, 2024). The following table presents the species that are listed as threatened or endangered or are candidates for listing that have been observed in McKinley County.

Insert 5-1: Federal- and State-Listed Species in McKinley County

Common Name	Scientific Name	Federal Status	State Status	Applicability to FWDA
Bald Eagle	*Haliaeetus leucocephalus*	Delisted, MBTA	Threatened, SGCN	Not applicable
Peregrine Falcon	*Falco peregrinus*	Delisted, MBTA	Threatened, SGCN	Not applicable
Least Tern	*Sternula antillarum*	Delisted, MBTA	Endangered	Not applicable
Costa's Hummingbird	*Calypte costae*	MBTA	Threatened, SGCN	Not applicable
Yellow-billed cuckoo (western population)	*Coccyzus americanus occidentalis*	Threatened, MBTA	SGCN	Not applicable
Mexican Spotted Owl	*Strix occidentalis lucida*	Threatened, MBTA	SGCN	Not applicable
Southwestern Willow Flycatcher	*Empidonax traillii extimus*	Endangered, MBTA	Endangered, SGCN	Not applicable
Gray Vireo	*Vireo vicinior*	MBTA	Threatened, SGCN	Applicable
Zuni Bluehead Sucker	*Catastomus discobolus yarrowi*	Endangered	Endangered, SGCN	Not applicable

SGCN – Species of Greatest Conservation Need
MBTA – Migratory Bird Treaty Act

Source: Biota Information System of New Mexico, New Mexico Game & Fish (Accessed 24Feb2024).

Each is discussed below:

Bald Eagle - Bald eagles are primarily water-oriented, and the majority of the populations occurring in New Mexico are found near streams and lakes (NMACP 2024). Because there are no bodies of water on or in the vicinity, bald eagles would unlikely be associated with the IF.

Peregrine Falcon - According to the New Mexico Avian Conservation Partner (NMACP, 2024), in New Mexico, almost all nests are constructed on ledges on relatively tall cliffs in remote areas with minimal human disturbance. The BISON-M distribution map shows peregrine falcon habitat on portions of Fort Wingate, which includes small portions of the IF. Enderson and Craig (1997) found home ranges in Colorado ranged from 358 – 1,508 square kilometers ($km^{2)}$ (about 88,000 - >350,000 acres). Although peregrine falcon habitat may occur in or near the IF, the potential contribution to a diet obtained within the IF would be inconsequential as the IF (assuming a sampling area of 180 acres) comprises only about 0.2% of the most conservative home range of the peregrine falcon.

Least Tern – Least terns in the interior of North America breed along major river systems and occasionally at lakes. The New Mexico population of least terns is found in Bitter Lake National Wildlife Reserve near Roswell in Chaves County (NMACP, 2024) and occasionally along the Pecos River valley. Because there are no bodies of water representative of least tern habitat on or in the vicinity of the Fort Wingate, least terns are not considered a concern for this evaluation. The BISON-M distribution map does not indicate any least tern habitat in the vicinity of Fort Wingate.

Costa's Hummingbird - Costa's Hummingbird is a desert scrub species of the southwestern United States and northern Mexico, with only a limited and irregular presence in southern New Mexico. It is reliant on nectar-producing native vegetation along the interface of desert and foothill/montane shrub habitats. In New Mexico, Costa's Hummingbird is an uncommon and sporadic breeder in the southwest and south-central mountains. It occurs most regularly in Guadalupe Canyon, and inside canyons along the lower Gila River from Cliff south. It may be irregular in other small desert ranges, especially in the San Andres mountains in Dona Ana County (NMACP, 2024). The BISON-M distribution map does not indicate any Costa's hummingbird habitat in the vicinity of Fort Wingate.

Yellow-billed Cuckoo - In New Mexico, the yellow-billed cuckoo is found in riparian zones with dense understory vegetation, most commonly in the south and along major drainages NMACP 2024). The BISON-M distribution map for the yellow-billed cuckoo does not indicate any habitat in the vicinity of Fort Wingate.

Mexican Spotted Owl - The Mexican Spotted Owl prefers mature forest with a closed canopy and complex vertical structure. In New Mexico, Spotted Owls occur in summer and winter throughout the state, except for in the eastern plains. They are more abundant in the south (NMACP 2024). BISON-M indicates there is FWS-listed critical habitat to the southeast of Fort Wingate. However, there is no habitat indicated on Fort Wingate or in the vicinity of the IF.

Southwestern Willow Flycatcher - The southwestern subspecies of the Willow Flycatcher has been federally listed as endangered since 1995, with critical habitat being designated in 2005. In New Mexico, Southwestern Willow Flycatcher breeds almost exclusively along the Gila River and Rio Grande. Scattered historical breeding records are also known from the Canadian, Chama, San Francisco, San Juan, and Zuni River drainages. Throughout the southwest, Southwestern willow flycatchers nest near lentic water, such as slow moving streams, river backwaters, oxbows, or marshy areas (NMACP, 2024).

The BISON-M distribution map for the southwestern willow flycatcher does not indicate any habitat in the vicinity of or within Fort Wingate.

Gray Vireo – The gray vireo is strongly associated with pinyon-juniper and scrub-oak habitat across its small breeding range in the southwestern United States and northern Mexico. In New Mexico, Gray Vireos are locally distributed across the western two-thirds of the state. Gray Vireos typically prefer open pinyon-juniper woodland or juniper savannah with a shrub component. In New Mexico, the species occurs in chaparral-juniper, pinyon-juniper, and pinyon-madrone associations. It also occurs in mid-elevation montane shrub habitats with rocky slopes and scattered conifers. Gray vireos arrive in New Mexico from mid to late-April, and generally depart by mid-August. Gray vireos are mostly insectivorous during the breeding season, foraging on the ground and in shrubs and trees up to 16 feet. (NMACP, 2024). BISON-M indicates potential gray vireo habitat within portions of the IF.

Zuni Bluehead Sucker – As reported in BISON-M, Zuni bluehead suckers generally occur in flowing pools and swift areas and streams. The distribution of C.d. yarrowi as of 2009 is limited to three localities and roughly two habitat types: Tampico Springs (headwater isolated spring), Agua Remora (headwater isolated spring), and Rio Nutria (canyon-bound river mainstem) with most fish found in the canyon-bound Rio Nutria. There are no aquatic habitats on or near the IF characteristic of habitat requirements of the Zuni bluehead sucker.

The U. S. Fish and Wildlife Service (USFWS) Information for Planning and Consultation (IPaC) tool was also accessed (USFWS, 2024). IPaC is a tool which generates a list of species and other resources such as critical habitats under USFWS jurisdiction that are known or expected to be on or near the project area (**Appendix D.2**, Attachment 3). The Mexican spotted owl, yellow-billed cuckoo, and Zuni bluehead sucker are included in the IPaC report. These were discussed above. Also included in the IPaC report are the monarch butterfly (Danaus plexippus – candidate) and Zuni fleabane (Erigeron rhizomatus – threatened). The golden eagle (Aguilia chrysaetos) was also noted. The golden eagle is not listed as a bird of conservation concern, but is protected under the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act. Each is discussed below:

Monarch butterfly – The monarch is a candidate species and not yet listed or proposed for listing. The Southwest Monarch Study (SMS, 2024) has studied monarch behavior in the southwestern United States, including New Mexico. To date, no overwintering monarchs have been observed in New Mexico, but have been documented during the early sprig migration in

late March and early April. By July, summer breeding monarchs are reported throughout the southwest range.

Monarch butterflies require healthy and abundant milkweed plants for laying eggs and as a food source for larvae or caterpillars. They also feed on the nectar of many flowers (USFWS, 2024b). Monarchs dwell above-ground and would not be expected to be directly exposed to soils. The monarch butterfly was not retained for evaluation in the IF.

Zuni fleabane – Zuni fleabane is an herbaceous perennial plant found in nearly barren detrital clay hillsides with soils derived from shales of the Chinle or Baca formations. This plant is known from three locations in the Zuni Mountains near Fort Wingate, 28 locations in the Sawtooth and northwest Datil mountains, and at least 3 locations in the Chuska Mountains on the Navajo Nation (New Mexico Rare Plant Technical Council, 2024). The potential presence of Zuni fleabane within the IF cannot be discounted. The Zuni fleabane will be evaluated as a part of the vegetative plant community.

Golden Eagle – The golden eagle is a carnivorous bird of prey. Food ranges from insects, small mammals, snakes, and turtles, to skunks, prairie dogs, marmots, ground squirrels, to rare extremes of full-grown deer, antelopes, and also great horned owls, magpies, domestic pigeons, and cranes. The golden eagle eats carrion but rarely attacks healthy pigs, sheep, deer, or other large mammals (BISON-M). Due to the wide-ranging foraging behavior of the golden eagle, the potential contribution of prey associated with the IF is considered inconsequential.

In conclusion, based on the behavior and habitat requirements of the species noted above, only the gray vireo and Zuni fleabane may potentially be present on or near the IF. Based on the diet of the gray vireo primarily as an insectivore, the horned lark will be used as a species representative of the gray vireo. The plant community will be the focus of the evaluation for the Zuni fleabane.

5.2.1.4 Preliminary Contaminants of Potential Ecological Concern

COPECs are chemicals which may pose a threat to individual species or biological communities. For the purposes of the Scoping Assessment, all chemicals known or suspected of being released at the site are considered COPECs. The preliminary COPECs identified for the IF included VOCs, SVOCs, PCBs, dioxins/furans, and inorganics. Individual COPECs are those constituents listed in **Appendix B**.

5.2.1.5 Ecological Conceptual Site Model

The Ecological Conceptual Site Model (ECSM) provided a summary of potentially complete exposure pathways, along with potentially exposed receptor types. The ECSM was used in conjunction with the scoping assessment to determine whether further ecological assessment (i.e., Screening-Level Assessment, Site-Specific Assessment) and/or interim measures are required (NMED, 2017).

As discussed previously, FWDA's primary mission was to receive, store, maintain, and ship explosives and military munitions, as well as disassemble and dispose of unserviceable or obsolete explosives and other military munitions. The HWMU within the IF was where all detonations and burns of explosives and munitions occurred. Based on the release mechanism and conditions within the IF (i.e., kickout and subsequent dispersion of MEC from OB/OD activities at the HWMU) resulting in releases to the surrounding area, the primary environmental medium impacted outside the HWMU was surface soil. Although subsurface soil could have been impacted by leaching and infiltration from surface soil for mobile constituents (such as VOCs), the potential was considered low as VOCs, if present, would likely quickly volatilize from surface soils, particularly in an arid environment. As a result, the inhalation pathway for potential receptors was considered incomplete. If mobile constituents in surface soil leached to subsurface soil, then exposures could be potentially complete, although this is considered a very minor pathway based on the release mechanism from the HWMU and was not evaluated.

Thus, the exposure medium of interest for this evaluation was surface soil. The potential routes by which ecological receptors may be exposed to site-related COPECs are illustrated in the ecological ECSM (**Figure 5-1**). The ECSM illustrates those exposure pathways that are potentially complete and were evaluated in the SLERA. These include the following:

- Terrestrial plants – direct contact with surface soils
- Birds and mammals – incidental ingestion of surface soil, and ingestion of forage or prey that have accumulated chemicals through bioaccumulative processes.

Some exposure pathways have been combined with others or cannot be quantitatively evaluated because of a lack of available information for the exposure evaluation. These were considered uncertainties in this SLERA. Examples of these potential exposure pathways include dermal and inhalation exposures for birds and mammals. Although these pathways are not quantitatively evaluated they were considered relatively minor exposure pathways relative to other exposure pathways. The inhalation pathway generally is not quantified for ecological receptors and was not considered a significant pathway (USEPA 1993). Additionally, while direct dermal contact with soil could potentially occur via digging or probing for food, most soil does not reach the epidermis of wildlife because of the presence of fur or feathers, and therefore, was not quantified. The inhalation and dermal exposure pathways may contribute to overall exposure, but their contribution is considered *de minimus*.

5.2.1.6 Scoping Assessment Summary

The Scoping Assessment identified ecological habitat at the site, preliminary COPECs, and potentially complete exposure pathways. The Technical Decision Point concluded from the Scoping Assessment is that further evaluation in a Tier 1 SLERA is warranted.

5.2.2 Tier 1 Screening-Level Ecological Risk Assessment

The Tier 1 SLERA uses information collected during the Scoping Assessment, and adds the following steps:

- Identification of species likely to be exposed to site-related chemicals, and, from among those, selection of representative receptors.
- Assessment of the potential magnitude of exposure using the maximum detected concentration and conservative Tier 1 exposure models.
- Identification of COPECs with the potential to cause adverse effects to ecological receptors based on conservative exposure assumptions and TRVs.

The detailed Tier 1 SLERA methodology is expanded in **Sections 5.2.2.1 to 5.2.2.7**, culminating in the Tier 1 evaluation results, uncertainties and conclusions (**Sections 5.2.2.8 to 5.2.2.10**).

5.2.2.1 Assessment Endpoints

Assessment endpoints (AEs) are the ecological values to be protected and are selected to ensure the survival and reproduction of all ecological receptors to maintain populations (NMED, 2017). NMED guidance (NMED 2017) has identified species or communities typical of most habitats within the State that should be considered for ecological risk assessment, which are: plant community, deer mouse (small mammalian omnivore), horned lark (avian omnivore), kit fox (mammalian carnivore), pronghorn (large game herbivore) and red-tailed hawk (avian carnivore).

Section 5.2.2.2 presents information supporting the decision that only four of the six categories of representative categories identified by NMED require evaluation in the IF area at FWDA. These receptor categories and their AEs are:

- Viability and Function of the Terrestrial Plant Community
- Survival, Growth and Reproduction of small mammalian omnivores (representative species deer mouse)
- Survival, Growth and Reproduction of avian omnivores (representative species horned lark)
- Survival, Growth and Reproduction of avian carnivore populations (representative species red-tailed hawk).
- Survival, Growth and Reproduction of mammalian carnivore populations (representative species kit fox).
- Survival, Growth and Reproduction of large herbivore populations (representative species pronghorn antelope).

5.2.2.2 Selection of Representative Receptor Species

As noted in **Section 5.2.2.1**, NMED guidance (NMED 2017) has identified species or communities typical of most habitats within the State that should be considered for ecological risk assessment: plant community, deer mouse (small mammalian omnivore), horned lark (avian

omnivore), kit fox (mammalian carnivore), pronghorn (large game herbivore) and red-tailed hawk (avian carnivore) requiring evaluation in the IF area at FWDA.

The kit fox, pronghorn and red-tailed hawk are wide-ranging receptors with home ranges of 2,767 acres, 3,422 acres and 1,770 acres, respectively. Per NMED guidance, risks to these wide-ranging species are assumed to be negligible when the areas of potential contamination are less than 10% of the species' home range. Approximately 180 acres were sampled within the IF. Based upon the IF acreage and the acreage associated with 10% of their home range, two receptors do not require further evaluation in the SLERA: 1) the kit fox – 10% of its home range is 279 acres, which is greater than the IF acreage; and 2) the pronghorn antelope - 10% of its home range would be 342 acres, which is also greater than the IF acreage.

Accounting for the home range exclusion, the kit fox and pronghorn antelope would not necessarily require evaluation. However, both have been retained to provide a relative risk contribution that might also be considered should data become available for other areas within or in proximity to the sampled IF area. Thus, the receptors retained for further evaluation within the IF are: plant community, deer mouse (small mammalian omnivore), horned lark (avian omnivore), red-tailed hawk (avian carnivore), kit fox (mammalian carnivore) and the pronghorn antelope (large mammalian herbivore). The plant community represents primary producers that form the foundation of the food chain, converting inorganic source materials into organic materials that are used as a food source by upper trophic level receptors. Plants also provide structure within the environment and habitat for other wildlife.

The deer mouse (*Peromyscus spp.*) was selected as a representative of the many small omnivorous mammals that may inhabit the site. Deer mouse is a collective name for a number of species of field mice or white-footed mice. In New Mexico, *Peromyscus maniculatus* is the most common of the genus (MNDGF 2016). Deer mice occur in many habitats and their diet may depend on location and season. According to USEPA (1993), diet items include vegetable matter (primarily, seeds, fruits, berries) and invertebrates (caterpillars of many species of insects, as well as adults). Per NMED Guidance (NMED, 2017), the deer mouse may be exposed to soils depths from 0-10 ft.

The horned lark (*Eremophila alpestris*) is found at many elevations in New Mexico deserts and prairies, but favors bare, dry ground and areas of short, sparse vegetation. The horned lark forages primarily on the ground and feeds on seeds and insects (Cornell 2024). As per NMED guidance, the proportion of plant matter to animal matter is 75:25. Per NMED Guidance (NMED, 2017), the horned larked may be exposed to surface soils (0-1 ft). The horned lark is considered an ecological receptor representing small birds.

As reported in NMED (2017), the red-tailed hawk (*Buteo jamaicensis*) is a top carnivore avian key receptor. The red-tailed hawk is widespread throughout New Mexico and is one of the most common birds of prey. It hunts primarily rodents, rabbits, birds, and reptiles. The red-tailed hawk has a large home range size (1770 acres). Per NMED Guidance (NMED, 2017) the red-tailed hawk may be exposed to surface soils (0-1 ft). The diet is based on a composition of 100% prey.

As described in NMED (2017), the kit fox (Vulpes macrotis) is native to the western United States and Mexico. Its diet consists mostly of small mammals, although its diet may also consist of plant matter during certain times of the year. It is selected as a key receptor because it is common in New Mexico, and the surrounding area at most sites in New Mexico provides suitable habitat for the kit fox. The kit fox has a large home range size (2767 acres) (Zoellick & Smith, 1992). Per NMED Guidance (NMED, 2017) kit fox may be exposed to both surface and subsurface soils (0-10 ft). The diet is based on a composition of 100% prey.

NMED (2017) describes the pronghorn antelope (Antilocapra americana) as a popular big game species that occurs in western Canada, United States, and northern Mexico. Its diet consists mainly of sagebrush and other shrubs, grasses, and forbs. The pronghorn is selected as a key receptor representative of large herbivorous species of wildlife. The pronghorn has a large home range size (3422 acres) (Reynolds, 1984). It is assumed that 100% of the diet is from grazing vegetation.

5.2.2.3 Data Usability

Prior to use in the human health and ecological risk assessments, all site data were validated and qualified following the QA/QC procedures described in the Work Plan (AECOM 2021). Data validation included procedures outlined in USEPA Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (USEPA 1989) and in the Guidance for Data Usability in Risk Assessment (USEPA 1990b). Sample results were assigned appropriate qualifiers during data validation, and applied in the SLERA as follows:

- Data were considered usable for risk assessment purposes if 1) they were not qualified or 2) were estimated (J-qualified).
- Data were not used if rejected (R-qualified) or if non-detect (U-qualified) in the field sample based on their presence in corresponding laboratory or field blanks. Other non-detect data for chemicals were considered useable in the risk assessments.
- Samples collected for QA/QC purposes (e.g., matrix spike/matrix spike duplicate) were used in the risk assessments.
- For duplicate samples, the higher of the parent and duplicate result was used.
- When calculating toxicity equivalents (TEQs) for dioxins/furans, non-detects were given a value of zero (see also **Section 5.2.2.7**).

5.2.2.4 Soil Intervals Used in the SLERA

NMED guidance recognizes two soil depths for ecological receptors: (1) animals that feed primarily at the surface or create only shallow burrows are considered to be exposed to surface and shallow-subsurface soil down to one foot. All representative receptors selected for this evaluation are considered to be exposed to surface soils. Plants and animals whose roots or burrows extend past one foot are considered to be exposed to soil down to 10 feet below the surface. Among the representative receptors selected for this evaluation, this applies to plants

and the deer mouse. As discussed in development of the ECSM **(Section 5.2.1.5)**, the HWMU was where all detonations and burns of explosives and munitions occurred. Based on the release mechanism and conditions within the IF (i.e., dispersion of MEC from OB/OD activities at the HWMU resulting in surface area releases) and the results of the MEC RA (recovered MEC was at or just below the surface), the primary environmental medium impacted was surface soil. Therefore, for purposes of this SLERA, only surface soils were used to evaluate potential exposures. The uncertainty associated with this assumption is discussed in the uncertainty analysis (**Section 5.2.2.9**). It is important to note that, as discussed in **Section 2.4.1**, the MEC items removed from the low density manually excavated grids of the IF during this RA, were typically recovered from depths less than 12 inches bgs and the deepest MEC item was recovered from a depth of 22 inches bgs. However, because historical accounts note that MEC could be deposited to depths up to 12 feet bgs within the IF Area, the potential for a remnant subsurface MEC/associated MC hazard cannot be completely discounted within the remediated and sampled IF grids/areas.

5.2.2.5 Comparison with Background

All metals data for the Inner Fence were collected using incremental sample methodology. The background data available for FWDA were based on discrete samples; therefore, it is not appropriate to use the FWDA background data for a quantitative comparison with incremental samples. For the Inner Fence SLERA, all detected metals were included in the quantitative assessment of risk. Potential non-site related risks associated with background were calculated (**Section 5.2.3.4**) to provide an additional line of supporting information for use in risk management decision making.

5.2.2.6 Ecological Screening Levels

NMED guidance (2017) has derived ecological screening levels (ESLs) for a number of typical representative species. These ESLs have been derived for New Mexico plant and animal species (specifically, the plant community, deer mouse, horned lark, kit fox, pronghorn, and red-tailed hawk) using conservative assumptions about exposure. In Tier 1, exposure concentrations are representative by the maximum detected concentration. Other conservative assumptions include minimum body weight and maximum dietary intake. Tier 1 TRVs are represented by a NOAEL. Preferential ESLs applied in Tier 1 were obtained directly from pre-calculated values presented in NMED guidance (NMED 2017). The ESLs are conservative by nature in indicating the potential for risk with the opportunity for refining conservative screening criteria with more realistic assumptions in a Tier 2 SLERA.

It is noted that ESLs were missing for several constituents which were detected in surface soils. These included:

- Acetone – plants
- 2-Butanone – horned lark, red-tailed hawk, plants
- Benzene – horned lark, red-tailed hawk

- Bis(2-ethylhexyl)phthalate – pronghorn, plants
- Bromomethane - deer mouse, horned lark, red-tailed hawk, kit fox, plants
- Chloromethane - deer mouse, horned lark, red-tailed hawk, kit fox, plants
- Chromium – plants
- Cyanide – plants
- Di-n-butylphthalate – pronghorn
- Dioxins/Furans – pronghorn, plants
- 2-Hexanone – plants
- Isopropyltoluene - deer mouse, horned lark, red-tailed hawk, kit fox, pronghorn, plants
- Toluene - horned lark, red-tailed hawk, pronghorn, plants
- 1,3-Trinitrobenzene – pronghorn
- 2,4,6-Trinitrotoluene – pronghorn
- 4-Amino-2,6-dinitrotoluene - pronghorn
- HMX - horned lark, red-tailed hawk, pronghorn
- RDX – pronghorn, plants
- Tetryl - horned lark, red-tailed hawk, pronghorn
- Antimony - horned lark, red-tailed hawk, pronghorn
- Barium - pronghorn
- Beryllium - horned lark, red-tailed hawk, pronghorn
- Cadmium – pronghorn
- Copper – pronghorn
- Mercury – pronghorn
- Selenium – pronghorn
- Thallium – pronghorn
- Cyanide - pronghorn
- Nitrate - deer mouse, horned lark, red-tailed hawk, kit fox, pronghorn, plants

A search was conducted from additional sources including the following:

- Los Alamos National Laboratory Ecorisk Database (Version 4.3) (N3B, 2022)
- USEPA Region 4 Ecological Risk Assessment Supplemental Guidance (USEPA, 2018)

- USEPA ECOTOX Knowledgebase (online database) (USEPA, 2024)
- USEPA Interim Ecological Soil Screening Level Documents (USEPA, 2003-2008)
- Toxicological Benchmarks for Contaminants of Potential Concern for Effects on Terrestrial Plants: 1997 Revision (Efroymson et al., 1997)
- Toxicological Benchmarks for Wildlife: 1996 Revision (Sample et al. 1996)

Additional ESLs were identified from the USEPA ECOTOX Knowledgebase for plants for bis(2-ethylhexyl)phthalate (1.07 mg/kg; Yuan et al. 2020), and RDX (6.33 mg/kg; Windfield et al. 2004). The highest no-observed effect level above the lowest lowest-observed effect level with the database was selected as an ESL.

USEPA publishes Ecological Soil Screening documents for aluminum and iron. Rather than numerical ESLs, pH levels in soils are noted as narrative screening endpoints. In well-aerated soils between pH 5 and 8, iron is not expected to be toxic to plants (USEPA 2003b). Iron is also not considered to be bioaccumulative and thus is not considered a concern for higher trophic levels (e.g., birds and mammals) (USEPA 2018). Similarly, USEPA soil screening guidance (USEPA 2003a) indicates aluminum is only a concern at sites where the soil pH is less than 5.5. The US Department of Agriculture (USDA) reports the Fort Wingate soil series is neutral (pH 7.0-7.2) in the surface soil horizons (USDA 2006). Therefore, neither aluminum nor iron were considered COPECs.

No additional information for the remaining COPECs and receptors was identified. In addition, no reliable surrogate values were identified. The absence of ESLs is discussed further in the Tier 1 Uncertainty Analysis (**Section 5.2.2.9**).

5.2.2.7 Exposure Concentrations

Tier 1 exposures were estimated using the maximum detected concentration of a chemical as the representative EPC within the IF.

The approach for evaluating dioxins/furans is different than that for other constituents. The relative toxicity of each congener is used to calculate an EPC to be compared with the ESL for TCDD, the most toxic congener. For each congener, a congener-specific TEF is applied to generate a TCDD TEQ for that congener. Van den Berg et al. (1998) has noted birds and mammals have slightly different sensitivities to some of the congeners; therefore, TEQs were calculated separately for mammals and birds. TEFs are summarized below (Van den Berg et al. 1998; Van den Berg et al. 2006):

Insert 5-2: Dioxin/Furan Toxicity Equivalency Factors

Dioxin and Furan Congeners	Mammalian TEF	Avian TEF
Chlorinated dibenzo-p-dioxins		
2,3,7,8-TCDD	1	1

Dioxin and Furan Congeners	Mammalian TEF	Avian TEF
1,2,3,7,8-PeCDD	1	1
1,2,3,4,7,8-HxCDD	0.1	0.05
1,2,3,6,7,8-HxCDD	0.1	0.01
1,2,3,7,8,9-HxCDD	0.1	0.1
1,2,3,4,6,7,8-HpCDD	0.01	0.001
OCDD	0.0003	0.0001
Chlorinated dibenzofurans		
2,3,7,8-TCDF	0.1	1
1,2,3,7,8-PeCDF	0.03	0.1
2,3,4,7,8-PeCDF	0.3	1
1,2,3,4,7,8-HxCDF	0.1	0.1
1,2,3,6,7,8-HxCDF	0.1	0.1
1,2,3,7,8,9-HxCDF	0.1	0.1
2,3,4,6,7,8-HxCDF	0.1	0.1
1,2,3,4,6,7,8-HpCDF	0.01	0.01
1,2,3,4,7,8,9-HpCDF	0.01	0.01
OCDF	0.0003	0.0001

For screening purposes in Tier 1, the maximum detected concentration of a congener was multiplied by the appropriate TEF to generate a toxicity equivalent for that congener. The congener TEQs were then summed for a total maximum-based TEQ for birds and mammals for screening against ESLs. Only detected values were included in calculation of the TEQs.

5.2.2.8 Tier 1 SLERA Results

By definition, the SLERA functions to screen and identify which sites, chemicals, pathways, and receptors may be a potential concern. Exceedance of an ESL does not imply that a risk is present since the ESL represents a "no-effects" concentration. However, a cumulative hazard (HI – hazard index) exceeding 1.0 indicates a potential for risk and that further analysis is warranted, generally in a Tier 2 SLERA.

In Tier 1, a screening-level hazard quotient (SLHQ) is calculated for each COPEC. The SLHQ is the ratio of the exposure concentration (maximum detected in Tier 1), to the chemical-specific ESL for each receptor.

$$SLHQ = (Maximum/ESL)$$

NMED recommends the summation of SLHQs for each representative receptor (referred to as the HI).

$$HI = SLHQ_1 + SLHQ_2 + \ldots + SLHQn$$

The HI is calculated for each representative receptor as the exposure pathways and sensitivities vary between receptors. If the HI is less than 1.0 for a receptor, further evaluation of that receptor

is not warranted. As with SLHQs, an HI greater than 1.0 does not automatically signify risk but that further evaluation is warranted.

Results of the Tier 1 SLERA results are provided in the following tables:

- **Table 5-1** – Tier 1 Screening Results for Plants
- **Table 5-2** – Tier 1 Screening Results for the Deer Mouse
- **Table 5-3** - Tier 1 Screening Results for the Horned Lark
- **Table 5-4** – Tier 1 Screening Results for the Red-Tailed Hawk
- **Table 5-5** – Tier 1 Screening Results for the Kit Fox
- **Table 5-6** – Tier 1 Screening Results for the Pronghorn Antelope

Resulting cumulative Tier 1 screening HIs are as follows:

- Plants – 35
- Deer Mouse - 35
- Horned Lark - 100
- Red-Tailed Hawk – 13
- Kit Fox – 7.9
- Pronghorn Antelope – 1.1

HIs exceeded one for each of the representative receptors in the Tier 1 evaluation. This was associated almost exclusively with metals in surface soils. For plants, SLHQs were highest for the following:

- Arsenic (0.48)
- Barium (6.9)
- Beryllium (0.72)
- Cobalt (0.63)
- Copper (9.6)
- Manganese (4.2)
- Nickel (0.55)
- Selenium (4.4)
- Thallium (4.0)
- Vanadium (70)
- Zinc (0.46).

Most notable COPEC-specific Tier 1 SLHQs for the deer mouse included the following:

- Antimony (1.2)
- Arsenic (0.9)
- Barium (1.7)
- Cadmium (0.51)
- Chromium (2.8)
- Cobalt (0.12)
- Copper (13)
- Lead (0.56)
- Manganese (2.0)
- Nickel (1.4)
- Selenium (1.8)
- Thallium (3.1)
- Vanadium (1.1)

Key COPEC-specific SLHQ results for the horned lark included the following:

- Arsenic (0.81)
- Barium (2.4)
- Cadmium (0.52)
- Chromium (4.9)
- Cobalt (0.23)
- Copper (35)
- Lead (3.1)
- Manganese (1.1)
- Mercury (21)
- Selenium (1.7)
- Vanadium (26)
- Zinc (0.23)

Notable inorganic SLHQs for the red-tailed hawk included the following:

- Barium (0.31)

- Chromium (0.64)
- Copper (4.6)
- Lead (0.40)
- Mercury (2.7)
- Selenium (0.22)
- Vanadium (3.4).

The highest SLHQs for the kit fox included the following:

- Antimony (0.26)
- Barium (0.39)
- Chromium (0.64)
- Copper (3.0)
- Lead (0.49)
- Manganese (0.45)
- Mercury (0.033)
- Nickel (0.31)
- Selenium (0.40)
- Thallium (0.70)
- Vanadium (0.25).

Although none of the individual constituents for the pronghorn antelope exceeded an SLHQ of 1, several contributed to a cumulative SLHQ slightly greater than one:

- Arsenic (0.24)
- Cobalt (0.14)
- Lead (0.14)
- Manganese (0.16)
- Silver (0.17)
- Vanadium (0.15)

All inorganics with a Tier 1 SLHQ above 0.1 were carried forward to Tier 2.

There are also noteworthy organic constituents as well. Among explosives constituents, the maximum concentration of methyl-2,4,6-trinitrophenylnitramine (tetryl) exceeded its ESL in sample P31F-SS-IS-SO-S526 (43J mg/kg), resulting in a Tier 1 SLHQ of 3.6 for the deer mouse.

This was a J-qualified (estimated) concentration in a single ISM sample replicate, and tetryl was not detected in the other two replicate samples collected at this location. This was the only detection of tetryl in the entirety of the IF (among a total of 167 ISM sample locations in which it was analyzed). This represents a detection frequency of less than 1%. The SLHQ for RDX was 1.4 for plants but was only detected in 2 of 167 sample locations (detection frequency 1%). Among semi-volatile organics, di-n-butylphthalate had a Tier 1 SLHQ of 0.11 for the horned lark. There were only two detects among 73 discrete samples (i.e., less than 3%), neither of which exceeded the Tier 1 ESL. Bis(2-ethylhexyl)phthalate had an SLHQ of 0.2 for plants and was detected in 1 of 73 samples (frequency of detection 1%). Based on the above discussion, none of the organic constituents were carried forward to Tier 2. Tier 1 SLHQs for all other organics were below 0.1 and were not retained for evaluation in Tier 2.

5.2.2.9 Uncertainties in the Tier 1 SLERA

The absence of ESLs for many COPECs represents a data gap that contributes to uncertainties in the risk evaluation. This could lead to an underestimate of potential risks. A list of detected analytes for which ESLs were unavailable was provided in **Section 5.2.2.6**.

VOC detections were limited to only a few analytes. Detections were infrequent, and due to fate and transport mechanisms, are unlikely to be persistent in surface soils. In addition, VOCs generally have low log-octanol water partition coefficients, rendering them unlikely to bioaccumulate and be a concern for higher trophic-level receptors. Similarly, SVOC detections were very infrequent, and of low concentration relative to TRVs where available. Although the absence of ESLs for detected analytes could result in an underestimate of potential risks, uncertainty is considered low.

It is also informative regarding the absence of detects among analytes for which no ESLs are available. For example, there were 84 sample analyses (including duplicates) at discrete sample locations, which were analyzed for VOCs, SVOCs, PCBs, dioxins/furans, and other analytes. In addition, explosives and metals were analyzed in ISM samples at up to 169 locations, and in excess of 500 replicates. It is compelling evidence based on the vast number of analytes not detected among all samples that non-detect constituents are not site related. Therefore, the uncertainty associated with the absence of ESLs is considered low.

The only plant ESL NMED provides for chromium is that for hexavalent chromium, which is much more toxic than trivalent chromium. The IF is not believed to have received plating waste or other material that may have contained hexavalent chromium. Therefore, use of the ESL for hexavalent chromium is likely to result in an overestimate of the plant SLHQ for chromium.

The NMED Tier 1 process incorporates conservative assumption to err on the side of over-estimating potential risks. Uncertainties in these assumptions that tend to overestimate potential risks include (but are not limited to): the extent to which the maximum represents the true exposure concentration, the incorporation of minimum body weights and maximum ingestion rates, the use of a conservative no-effects value as a screening criterion, and the contribution of background to exposure estimates for metals.

5.2.2.10 Tier 1 SLERA Conclusions

It is concluded that a Tier 2 Evaluation is warranted for specific metals. **Insert 5-3 below** summarizes the COPECs carried forward for the Tier 2 evaluation.

Insert 5-3: Summary of Tier 2 COPECs

Birds and Mammalian Receptors of Interest	Plants
Antimony	Arsenic
Arsenic	Barium
Barium	Beryllium
Beryllium	Cadmium
Cadmium	Cobalt
Chromium (Total)	Copper
Cobalt	Lead
Copper	Manganese
Lead	Nickel
Manganese	Selenium
Mercury (elemental)	Thallium
Nickel	Vanadium
Selenium	Zinc
Thallium	
Vanadium	
Zinc	

5.2.3 Tier 2 Screening-Level Ecological Risk Assessment Methodology

In the Tier 2 SLERA, less conservative methodologies are applied. A more reasonable representation of the exposure concentration is used (**Section 5.2.3.2**) and NMED recommends a LOAEL TRV as a benchmark more representative of population risks (**Section 5.2.3.3**).

NMED does not have LOAEL-based ESLs for receptors other than plants. Rather, an ingestion exposure model approach is recommended by NMED (2017) for higher trophic level receptors. The model is used to estimate an average exposure dose to be compared with an oral LOAEL TRV. This dose is generally expressed as:

$$\text{Exposure Dose} = (\text{Cplant} \times \text{IRplant} + \text{Cinv} \times \text{IRinv} + \text{Cprey} \times \text{IRprey}) \times \text{AUF/BW}$$

Where:

Exposure dose	=	Ingested dose (mg COPEC per kg of body weight per day)
Cplant	=	Concentration of COPEC in plants (mg/kg dw)
Cinv	=	Concentration of COPEC in invertebrates (mg/kg dw)
Cprey	=	Concentration of COPEC in prey (mg/kg dw)
Dw	=	Dry weight

IRplant	=	Ingestion rate of plants (mg/day dw)
IRinv	=	Ingestion rate of invertebrates (mg/day dw)
IRprey	=	Ingestion rate of prey (mg/day dw)
AUF	=	Are use factor (unitless ratio of site area to home range)
BW	=	Body weight (kg)

This model was adjusted for each receptor to reflect receptor-specific body weights, ingestion rates and dietary composition of plants, invertebrates and prey, and chemical-specific uptake of COPECs into each of the diet items, consistent with NMED (2017). Specifically, the average adult body weights and average daily ingestion rates were applied. The receptor assumptions used for the Tier 2 SLERA are presented in **Table 5-7**.

The AUF is a unitless ratio of the ecological exposure area (EEA) to the home range of the receptor. The entirety of the IF (*sans* the HWMU area) is estimated at 251 acres. A total of 180 acres was sampled during this investigation. Habitat is relatively uniform within the area of interest. The home ranges (foraging ranges) for the birds and mammals representing the assessment endpoints are: deer mouse, 0.3 acres; horned lark, 4.0 acres; and red-tailed hawk, 1,770 acres. Although the home ranges of the deer mouse and horned lark are less than the sampled area, the goal in the ecological risk assessment is to maintain populations, which is also applicable to plants. Therefore, the entirety of the sampled area of 180 acres was selected as the EEA for this evaluation. An AUF of 0.102 was applied for the red-tailed hawk, assuming a total foraging area of 1,770 acres (180 acres/1,770 acres = 0.102). An AUF of 0.105 was applied for the kit fox, assuming a total foraging area of 1,713 acres (180 acres/1,713 acres = 0.105). An AUF of 0.0526 was applied for the pronghorn, assuming a total foraging area of 3,422 acres (180 acres/3,422 acres = 0.0526). An AUF of one is applied if the area of the home range is less than the area of the EEA. Therefore, an AUF of one was applied in Tier 2 for the deer mouse and horned lark.

An ingestion model is not applied for plants. Rather, the exposure concentration is calculated based on the soil concentration.

5.2.3.1 Bio-Uptake Factors

Concentrations of COPECs in dietary items (plant and animal matter) were predicted by applying biouptake factors or algorithms relating concentrations in soil with concentrations in dietary tissues. While NMED (2015) recommends specific plant uptake factors for metals, they are based on a single source (Baes et al. 1984). The source NMED recommends for uptake into animal matter also contains a compilation of plant uptake factors: Attachment 4-1, Exposure Factors and Bioaccumulation Models for Derivation of Wildlife Eco-SSLs (USEPA 2007a) as part of the Guidance for Developing Ecological Soil Screening Levels (Eco-SSLs). Since USEPA (2007) presents uptake factors that include empirical data from Baes et al. (1984), as well as more recent data, the uptake factors (or algorithms) from USEPA (2007) were

preferentially selected for this SLERA. A summary of uptake factors and their sources is presented in **Table 5-8**.

5.2.3.2 Exposure Point Concentrations

In the Tier 2 analyses, NMED recommends a more reasonable EPC as represented by the lower of the 95% UCL of the mean or the maximum. As the COPECs retained in Tier 2 were from incremental samples, the ITRC incremental sample calculator was used to calculate 95% UCLs. A summary of Tier 2 EPCs is presented in **Table 5-9**. Detailed calculations are provided in **Appendix D.3**.

5.2.3.3 Effects Assessment

The potential for toxic effects is identified by comparing site EPCs or doses with TRVs. NMED (2017) guidance was the source of the LOAEL-based TRVs applied in the Tier 2 SLERA.

5.2.3.4 Tier 2 Risk Characterization

In order to evaluate whether exposures may exceed potential effects levels, the exposure concentration or dose in Tier 2 is compared with a LOAEL TRV to provide a risk estimation. For each COPEC and receptor, Similar to Tier 1, Tier 2 SLHQs are generated by dividing the exposure dose or concentration by the TRV. The uncertainties associated with assumptions used in estimating potential risks are discussed to qualify the confidence in the risk estimation. The uncertainties (**Section 5.2.3.5**) are subsequently discussed in the context of the SLHQs and HIs in a final SLERA risk characterization summary (**Section 5.2.3.6**).

Tier 2 SLERA results are provided in the following tables:

- **Table 5-10** – Tier 2 Average Daily Doses
- **Table 5-11** – Tier 2 HIs

Resulting Tier 2 screening HIs are as follows:

- Plants – 2.3
- Deer Mouse – 0.32
- Horned Lark – 2.0
- Red-Tailed Hawk – 0.0091
- Kit Fox – 0.010
- Pronghorn Antelope – 0.0017

HIs for the deer mouse, red-tailed hawk, kit fox and pronghorn antelope were less than one, indicating no unacceptable risks are present for these receptors and the assessment endpoints they represent. The HI for plants (2.3) was influenced mostly by the SLHQ for barium (0.97),

and to a lesser extent manganese (0.36) and selenium (0.35). For the horned lark, the HI was influenced by SLHQs for vanadium (0.62), copper (0.46), selenium (0.34), lead (0.24), and mercury (0.18). However, each of these results was also highly influenced by background metals concentrations. In order to better quantify this, the Tier 2 exposure model was used to estimate background HIs. The 95% UCL of background metal concentrations, obtained from the Soil Background Study and Data Evaluation Report (Shaw 2010) were placed in the Tier 2 exposure model.

Calculated risks associated solely based on background concentrations are provided in the following tables:

- **Table 5-12** – Background Average Daily Doses for the Bird and Mammal Receptors of Interest
- **Table 5-13** – Background HIs for Plants and Bird and Mammal Receptors of Interest

A summary of calculated risks associated solely with background concentration in comparison with IF HIs are as follows:

Comparison of IF and Background Hazard Indices

Receptor of Interest	Inner Fence Area	Background
Plants	2.3	1.7
Deer Mouse	0.32	0.14
Horned Lark	2.0	1.2
Red-Tailed Hawk	0.0091	0.0068
Kit Fox	0.010	0.0067
Pronghorn Antelope	0.0017	0.0021

5.2.3.5 Tier 2 Uncertainty Analysis

Many of the uncertainties in Tier 2 are common to Tier 1 as discussed previously (see **Section 5.2.2.9**). The absence of ESLs for some COPECs represents a data gap that contributes to uncertainties in the risk evaluation and could result in an underestimate of potential risks. NOAELs were applied during Tier 1; however, LOAEL TRVs as applied in Tier 2 reduce the potential for overestimation of potential risks. In addition, there are many possible modes of toxicity so summing SLHQs when the receptor-specific mode of toxicity cannot be readily defined and limits the interpretation of the results. Summation of the SLHQs also does not take into account additive, synergistic or antagonistic effects among the COPECs. These limitations could lead to an overestimate or underestimate of potential risks.

Exposure concentrations in the SLERA were derived from surface soils and did not include subsurface soils. The rationale for focusing on surface soils was described in development of the

ECSM (see **Section 5.2.1.5**). The potential that COPECs may be present in subsurface soils could lead to an underestimate in potential site risks.

The entirety of the sampled area of 180 acres was selected as the EEA for this evaluation. For receptors with home ranges less than 180 acres (e.g., deer mouse, horned lark), as well as plants, potential risks may be underestimated within subareas of the EEA. However, because the evaluation is to consider the population as a whole, uncertainty is considered low.

5.2.3.6 Tier 2 Risk Characterization Summary

Tier 2 HIs were less than one for the deer mouse, red-tailed hawk, kit fox, and pronghorn antelope. Tier 2 HIs slightly exceeded one for the horned lark (2.0) and plants (2.3) (see **Section 5.2.3.4** and **Table 5-11**). An HI equal to or in excess of 1 does not indicate that adverse effects will occur, but suggests there is a low potential for adverse effects.

5.2.4 Inner Fence Tier 1 and Tier 2 SLERA Conclusions

A Scoping Assessment concluded that the IF contains terrestrial ecological habitat and potentially complete pathways for ecological receptors. A summary of Tier 1 and Tier 2 SLHQs and HIs is presented in **Table 5-14**. Calculated risks associated with background exposures are provided as an additional line of information for use in risk management decision making. The following conclusions are drawn for each of the assessment endpoints identified for the evaluation.

Viability and Function of the Terrestrial Plant Community – The Tier 2 HI for the plant community in the IF was 2.3. A Tier 2 HI equal to or in excess of 1 does not indicate that adverse effects will occur, but suggests there is a low potential for adverse effects. This is also relevant to evaluation of the Zuni fleabane, which was identified as a component of the plant community. The Zuni fleabane is listed as a federally threatened species. It is also notable that the background HI was 1.2, which also suggests a potential for adverse effects related to non-site related naturally occurring conditions, and highlights the uncertainty in the risk evaluation.

Survival, Growth and Reproduction of Omnivorous Mammalian Populations – The deer mouse was selected as a representative of omnivorous mammals. The Tier 2 HI was less than one in the IF (0.32). It is concluded that there are no unacceptable risks to omnivorous mammalian populations.

Survival, Growth and Reproduction of Omnivorous Avian Populations – Omnivorous birds were represented by the horned lark. The Tier 2 HI for the horned lark was 2.0. An HI equal to or in excess of 1 does not indicate that adverse effects will occur, but there is a low potential for adverse effects. The horned lark was also used as a species representative of the gray vireo. The gray vireo is a state-listed threatened species and is listed under the Federal Migratory Bird Treaty Act. It is also notable that the background HI was 1.2, which also suggests a potential for adverse effects related to non-site related naturally occurring conditions, and highlights the uncertainty in the risk evaluation.

Survival, Growth and Reproduction of Carnivorous Avian Populations - The red-tailed hawk was selected as a representative of carnivorous birds. The Tier 2 HI was 0.009. It is concluded that there are no unacceptable risks to carnivorous avian populations.

Survival, Growth and Reproduction of Carnivorous Mammal Populations - The kit fox was selected as a representative of carnivorous mammals. The Tier 2 HI was 0.010. It is concluded that there are no unacceptable risks to carnivorous mammal populations.

Survival, Growth and Reproduction of Large Herbivorous Mammal Populations - The pronghorn antelope was selected as a representative of large herbivorous mammals. The Tier 2 HI was 0.0017. It is concluded that there are no unacceptable risks to large herbivorous mammal populations.

					Cumulative Plant Hazard		**35**
					Exceeds Target Level		**Y**

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update.

2) Chromium screening value is for Total Chromium.

3) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

Shaded values exceed ecological screening levels.

CAS = Chemical Abstracts Service

ESL = Ecological Screening Level

J = Estimated

mg/kg = milligrams per kilogram

NA = Not applicable

NS = No Standard

U = Nondetect

							Cumulative Deer Mouse Hazard		**35**
							Exceeds Target Level		**Y**

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update.

2) Chromium screening value is for Total Chromium.

3) Toxicity data for the dioxin and furan congeners were assessed using the 2005 World Health Organization toxicity equivalency factors (TEF) from Van den berg, et al (2006). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the NMED SSL for 2,3,7,8-tetrachlorodibenz-p-dioxin (TCDD). (NMED 2017, Revised).

4) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

CAS = Chemical Abstracts Service

ESL = Ecological Screening Level

J = Estimated

mg/kg = milligrams per kilogram

NA = Not applicable

NS = No Standard

TEF = Toxicity Equivalency Factor

TEQ = Toxic equivalency quotient

U = Nondetect

							Cumulative Horned Lark Hazard		**100**
							Exceeds Target Level		**Y**

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update, except TEQ birds from USEPA Region 4 (2018)

2) Chromium screening value is for Total Chromium.

3) Toxicity data for the dioxin and furan congeners were assessed using toxicity equivalency factors (TEF) from Van den berg, et al (1998). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the USEPA Region 4 ESL for birds USEPA (2018).

4) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

CAS = Chemical Abstracts Service

ESL = Ecological Screening Level

J = Estimated

mg/kg = milligrams per kilogram

NA = Not applicable

NS = No Standard

TEF = Toxicity Equivalency Factor

TEQ = Toxic equivalency quotient

U = Nondetect

							Cumulative Red-Tailed Hawk Hazard		**13**
							Exceeds Target Level		**Y**

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update, except TEQ birds from USEPA Region 4 (2018)

2) Chromium screening value is for Total Chromium.

3) Toxicity data for the dioxin and furan congeners were assessed using toxicity equivalency factors (TEF) from Van den berg, et al (1998). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the USEPA Region 4 ESL for birds USEPA (2018).

4) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

CAS = Chemical Abstracts Service
ESL = Ecological Screening Level
J = Estimated
mg/kg = milligrams per kilogram
NA = Not applicable
NS = No Standard
TEF = Toxicity Equivalency Factor
TEQ = Toxic equivalency quotient
U = Nondetect

							Cumulative Kit Fox Hazard		**7.9**
							Exceeds Target Level		**Y**

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update.

2) Chromium screening value is for Total Chromium.

3) Toxicity data for the dioxin and furan congeners were assessed using the 2005 World Health Organization toxicity equivalency factors (TEF) from Van den berg, et al (2006). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the NMED SSL for 2,3,7,8-tetrachlorodibenz-p-dioxin (TCDD). (NMED 2017, Revised).

4) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

CAS = Chemical Abstracts Service

ESL = Ecological Screening Level

J = Estimated

mg/kg = milligrams per kilogram

NA = Not applicable

NS = No Standard

TEF = Toxicity Equivalency Factor

TEQ = Toxic equivalency quotient

U = Nondetect

Notes:

1) New Mexico Environment Department Ecological Soil Screening Levels. March 2017 Update.

2) Chromium screening value is for Total Chromium.

3) Toxicity data for the dioxin and furan congeners were assessed using the 2005 World Health Organization toxicity equivalency factors (TEF) from Van den berg, et al (2006). TEFs were applied to the analytical results and summed for each sample resulting in a toxicity equivalent (TEQ). The TEQ was then compared to the NMED SSL for 2,3,7,8-tetrachlorodibenz-p-dioxin (TCDD). (NMED 2017, Revised).

4) pH-dependent. Not a concern at the Inner Fence Area. See Text.

TEQ maximum was calculated using the ProUCL dataset. See **Appendix D, Attachment 3.

CAS = Chemical Abstracts Service

ESL = Ecological Screening Level

J = Estimated

mg/kg = milligrams per kilogram

NA = Not applicable

NS = No Standard

TEF = Toxicity Equivalency Factor

TEQ = Toxic equivalency quotient

U = Nondetect

TABLE 5-7
TIER 2 EXPOSURE FACTORS FOR BIRD AND MAMMAL RECEPTORS OF INTEREST
FORT WINGATE DEPOT ACTIVITY
MCKINLEY COUNTY, NEW MEXICO

Receptor of Interest	Guild	Body Weight (kg)	Foraging Territory (acres)	Food Ingestion Rate Plants (kg dw/day)	Food Ingestion Rate Invertebrates (kg dw/day)	Food Ingestion Rate Prey (kg dw/day)	Soil Ingestion Rate (kg dw/day)
Deer Mouse	Omnivore	0.02	0.30	0.000660	0.000220	0	0.000018
Horned Lark	Omnivore	0.033	4.00	0.00572	0.00198	0	0.00077
Red-Tailed Hawk	Carnivore	1.1	1770	0	0	0.0220	0.0004
Kit Fox	Carnivore	2	1713	0	0	0.0286	0.0008
Pronghorn	Herbivore	50	3422	0.308	0	0	0.006

All values presented are from NMED (2017). Food ingestion rates presented in NMED (2017) are in kg food wet weight/day. These have been converted to dry weight using a wet-weight to dry-weight conversion factor of 0.22 per NMED (2017)

Notes:
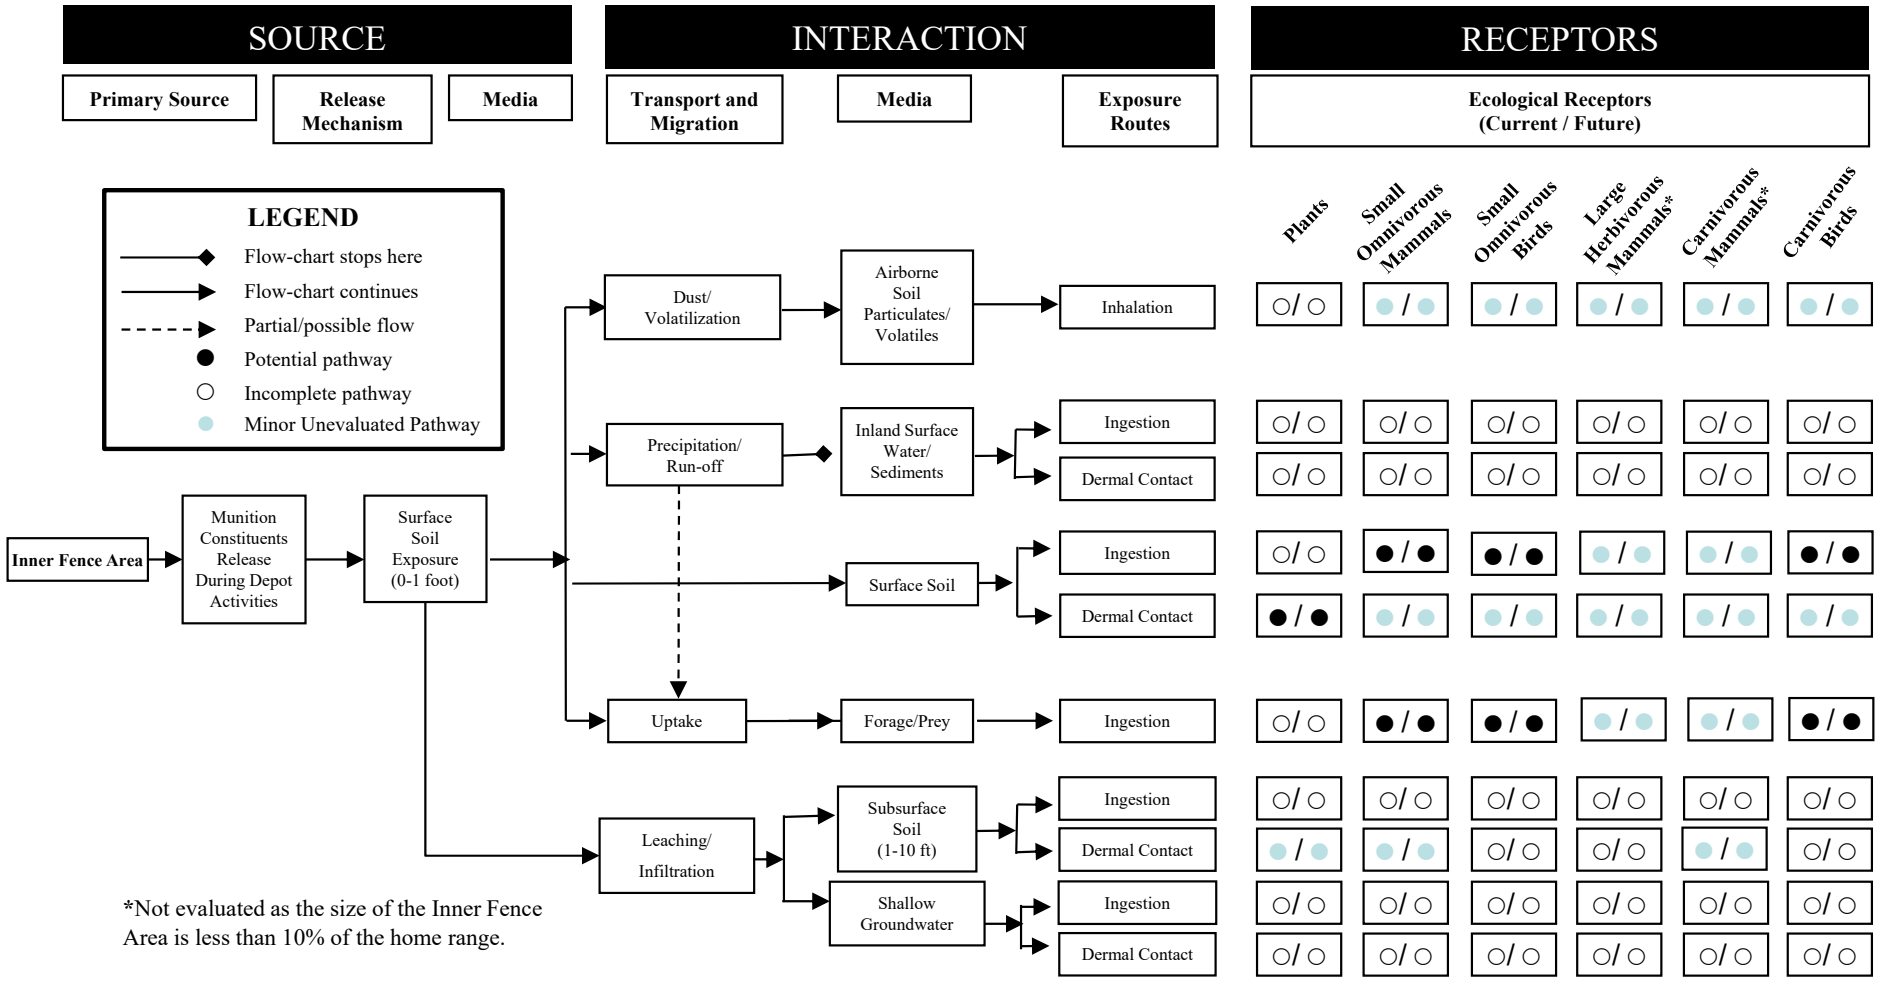
All SLHQs and HIs are unitless
Only those COPECs carried forward to Tier 2 are presented.
Tier 1 values from Tables 5-1 through 5-4.
Tier 2 IF values from Table 5-11
Tier 2 Background values from Table 5-13.
NA - Not available
SLHQ - Screening Level Hazard Quotient

FIGURE 5-1
INNER FENCE AREA ECOLOGICAL CONCEPTUAL SITE MODEL
FORT WINGATE DEPOT ACTIVITY, McKINLEY COUNTY, NEW MEXICO



*Not evaluated as the size of the Inner Fence Area is less than 10% of the home range.

Representative receptors:
Small omnivorous mammals – Deer mouse
Small omnivorous birds – Horned lark
Large herbivorous mammals – Pronghorn
Carnivorous mammals – Kit fox
Carnivorous birds – Red-tailed hawk

The subsurface RA of the IF was initiated on August 28, 2017, and ceased in December 2020 due to concerns for personnel safety. The anomaly densities that were being encountered were too high to safely identify and manually resolve as single point anomalies. It was concluded that the anomaly densities would continue to increase as the work moved closer to the HWMU and the remainder of the IF subsurface RA would require alternative methods to complete. Subsurface removal operations were completed in 721 grids within the IF.

- Over 1.4 million anomalies were manually investigated
- Over 338,800 pounds of MD was recovered
- 16,578 MEC items were identified and destroyed

The majority of MEC items recovered were PD and base detonating BD fuzes, 37 millimeter (mm) and 40 mm projectiles. These four items account for nearly 85 percent of the MEC recovered from the IF. As discussed in **Section 3.1**, MEC was only removed from the completed IF grids to a maximum depth of 22 inches, however, MEC has historically been recovered from within Parcel 3 to depths up to 12 feet bgs. As a result, the presence of residual MEC cannot be discounted (but is considered unlikely) from depths between approximately 22 inches and 12 feet bgs, within the completed IF grids. In addition, the presence of subsurface MEC (i.e., up to 12 feet bgs) is also considered possible within the IF grids that were excluded from the RA due to safety concerns. It is also possible that this residual subsurface MEC hazard could extend beyond the southern and western boundaries of the IF. As a result, additional remedial actions and/or appropriate land use controls may be warranted for these areas and depths.

Incremental soil characterization samples were collected from within low-density area and buffer area grids within the IF and were analyzed for explosives and metals. Additional discrete samples were also collected from within the buffer area grids and were analyzed for VOCs, SVOCs, NDMA, metals, PCBs, nitrate, cyanide, dioxins/furans, and perchlorate.

A human health risk screen was completed (**Section 4**) for the Buffer Area (immediately bounding the HWMU/high-density MEC area) and the Low-Density Area (adjacent to the Buffer Area). Each area was comprised of multiple 100-foot by 100-foot grids which were individually sampled for MC. For human exposures, the grids represent a more likely exposure area than the larger Buffer Area and Low-Density Area because they are closer to the size of a residential lot. Therefore, excess cancer risks and hazards were estimated for each sampled grid in the Buffer Area and Low-Density Area. Buffer Area grids were sampled for VOCs, SVOCs, NDMA, PCBs, nitrate, cyanide, dioxins/furans, and perchlorate via discrete sampling methods and TAL metals and explosives via ISM. Low-density area grids were sampled for TAL metals and explosives via ISM.

As discussed in **Sections 4.1.2**, **4.2.1**, and **4.2.2**, the IF Area sample results documented for metals in this Report were collected using an incremental sampling approach. Based on this, the qualitative comparison of resulting incremental metals concentrations to FWDA background levels previously established for FWDA based on discrete sample data for metals (**Table 4-3**) is considered preliminary and additional evaluation is warranted. In addition, numerous screening

levels were undefined/unavailable for appropriately evaluating the potential migration of soil contaminants to groundwater at the site, so additional evaluation of this potential pathway is also warranted for the IF Area. Based on this, additional evaluation of these concerns will be included in a forthcoming Parcel 3 RFI Work Plan that will include additional sampling and risk evaluation of potentially impacted media within the inner fence area. In addition, evaluation of potential impacts to groundwater will be addressed in the forthcoming Parcel 3 Groundwater RFI Supplemental Sampling Report.

The results of the human health risk assessment that will be further evaluated as warranted during a subsequent RFI are summarized as follows:

- Sixty-two low density grids had hazard indices greater than 1.0 for the residential scenario and 15 low density grids had hazard indices greater than 1.0 for the construction worker scenario. The primary contributors for all these grids were metals (aluminum, arsenic, aluminum, barium, chromium, cobalt, iron, manganese, and/or thallium). The target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0 for organics. Therefore, these grids were considered to pose no unacceptable adverse health effects to residents or construction workers for organics. However, additional evaluation of metals concentrations in site media will be included in the forthcoming RFI as discussed above.
- Seventy-seven low density grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese resulted in hazard greater than 1.0 for the construction worker scenario. Therefore, these grids may pose unacceptable adverse health effects for construction workers. However, the low density grid manganese concentrations range was within the FWDA background range and the USGS reference ranges. Therefore, manganese concentrations in these low density grids were potentially naturally-occurring, but additional evaluation of these results is planned at the IF Area during a forthcoming RFI as discussed above.
- Low-density area Grid AL39 had a cancer risk of 1.2E-05 for residents which exceeded the NMED target cancer risk of 1.0E-05. The primary contributor was arsenic. The maximum detected arsenic concentration was within the FWDA background range and the USGS metal reference study ranges. Therefore, arsenic in Grid AL39 is not considered likely to pose any unacceptable cancer risks for residents. However, additional evaluation of these results is planned at the IF Area during a forthcoming RFI as discussed above.
- Seventeen buffer area grids had hazard indices greater than 1.0 for the residential scenario and 16 grids had hazard indices greater than 1.0 for the construction worker scenario. The primary contributors for all these grids were metals (aluminum, arsenic, aluminum, barium, chromium, cobalt, iron, manganese, and/or thallium). Although the target organ assessments for these grids showed that no target organ/system had a hazard index greater than 1.0, additional evaluation of metals results is planned at the IF during a forthcoming RFI as discussed above.
- Thirty-five buffer area grids had target organ assessments where the additive effects on the nervous system by aluminum and manganese resulted in hazard greater than 1.0 for the

construction worker scenario. Twenty buffer area grids had hazard indices greater than 1.0 due to manganese. Although the buffer area grid manganese concentrations were within the FWDA background range and the USGS metal reference ranges (i.e., may be naturally occurring), additional evaluation of metals results is planned at the IF during a forthcoming RFI as discussed above.

- All lead concentrations from the low-density and buffer area grids were below the NMED residential SSLs; therefore, no further evaluation of lead concentrations was necessary.

All other low-density area and buffer area grids were below the NMED target cancer risk of 1.0E-05 and had HIs less than the NMED target HI of 1.0. Based on these results, surface soils within the low-density and the buffer grids of the IF Area are not likely to pose any unacceptable cancer risks or adverse health effects for residents, site workers, or construction workers.

An ecological risk assessment was also completed (**Section 5**) and determined that the IF contains terrestrial ecological habitat and potentially complete pathways for ecological receptors. Metals were identified as posing the greatest ecological risk potential within the IF following a Tier 1 evaluation. As a result, a Tier 2 SLERA was also completed and concluded that there are no unacceptable ecological risks to the viabilities and functions of the terrestrial plant community, omnivorous bird populations, omnivorous mammal populations or carnivorous bird populations within the IF Area.

Date Collected	June 5, 2023		
Semivolatile Organic Compounds (mg/kg), continued			
4-Chlorophenyl-phenylether	-		
4-Nitroaniline	-		
4-Nitrophenol	-		
Acenaphthene	-		
Acenaphthylene	-		
Anthracene	-		
Benzo(a)anthracene	-		
Benzo(a)pyrene	-		
Benzo(b)fluoranthene	-		
Benzo(g,h,i)perylene	-		
Benzo(k)fluoranthene	-		
Benzoic acid	-		
Benzyl Alcohol	-		
Bis(2-chloro-1-methylethyl) ether	-		
Bis(2-chloroethoxy)methane	-		
Bis(2-chloroethyl)ether	-		
Bis(2-ethylhexyl)phthalate	-		
Butyl benzyl phthalate	-		
Carbazole	-		
Chrysene	-		
Di-n-butyl phthalate	-		
Di-n-octyl phthalate	-		
Dibenz(a,h)anthracene	-		
Dibenzofuran	-		
Diethyl phthalate	-		
Dimethyl phthalate	-		
Fluoranthene	-		
Fluorene	-		
Hexachlorobenzene	-		
Hexachlorobutadiene	-		
Hexachloroethane	-		
Indeno(1,2,3-cd)pyrene	-		
Isophorone	-		
n-Nitroso-di-n-propylamine	-		
n-Nitrosodimethylamine	-		
n-Nitrosodiphenylamine	-		
Naphthalene	-		
Nitrobenzene	-		
Pentachlorophenol	-		
Phenanthrene	-		
Phenol	-		
Pyrene	-		
Explosives (mg/kg)

1,2,3,7,8-Pentachlorodibenzo-p-dioxin (PeCDD)	-		
2,3,4,6,7,8-Hexachlorodibenzofuran (HxCDF)	-		
2,3,4,7,8-Pentachlorodibenzofuran (PeCDF)	-		
2,3,7,8-Tetrachlorodibenzofuran (TCDF)	-		
2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD)	-		

TABLE B-N22
ANALYTICAL RESULTS FOR GRID N22
FORT WINGATE DEPOT ACTIVITY INNER FENCE
MCKINLEY COUNTY, NEW MEXICO

Field Identification	N22		
Sample Name	P3IF-SS-IS-SO-N622		
Date Collected	June 15, 2023		
Metals (mg/kg)			
Aluminum	19000	4	
Antimony	0.15	0.15	U
Arsenic	0.78	0.3	
Barium	480	0.2	
Beryllium	1.3	0.3	
Cadmium	0.46	0.08	
Calcium (Ca)	39000	15	
Chromium	11	0.2	
Cobalt	4.2	0.08	
Copper	76	0.2	
Iron (Fe)	13000	8	
Lead	12	0.05	
Magnesium (Mg)	6400	5	
Manganese (Mn)	620	0.08	
Mercury	0.019	0.042	J
Nickel	10	0.2	
Potassium (K)	1900	8	
Selenium	0.91	0.1	
Silver	0.022	0.05	J
Sodium (Na)	63	8	
Thallium	0.08	0.05	J
Vanadium	8	0.1	
Zinc	21	1.5	
Other Parameters (mg/kg)			
Cyanide (CN-)	-		
Nitrate	-		
Perchlorate	-		

Notes:
< = less than LOD
- = not analyzed
LOD = LOD
mg/kg = milligrams per kilogram
Qual = qualifier
J = estimated
U = not detected
UJ = estimated nondetect
